Table 80  
q56) You indicated that you are a current user of cigarettes and/or rolling cigarettes. The following questions in this section will ask you about your current and past cigarette/rolling cigarette usage. Approximately how long have you smoked cigarettes or rolling tobacco? If you have smoked for several periods, and quit in between, we ask you to please state the total time you have smoked. For example if you smoked for 5 years, quit for 1 year, and have smoked for the past 2 years - please indicate 7 years.

Table 116  
q96) Approximately how long did you smoke cigarettes or rolling tobacco before quitting? If you had smoked for several periods, and quit in between, we ask you to please state the total time you had smoked. For example if you smoked for 5 years, quit for 1 year, smoked for 2 more years and then quit - please indicate 7 years.

Q1/Q2 2016

Table 917  
q312) Approximately how long did you use moist snuff before quitting? If you had used moist snuff for several periods, and quit in between, we ask you to please state the total time you had used moist snuff. For example if you dipped for 5 years, quit for 1 year, dipped for 2 more years and then quit - please indicate 7 years.

Table 967

q351) You indicated that you are a current user of cigarillos. The following questions in this section will ask you about your cigarillo usage. How long have you been smoking cigarillos? If you have used cigarillos for several periods, and quit in between, we ask you to please state the total time you have used cigarillos. For example if you used cigarillos for 5 years, quit for 1 year, and have used cigarillos for the past 2 years - please indicate 7 years.

Table 979  
q370) You indicated that you are a current user of chewing tobacco. The following questions in this section will ask you about your chewing tobacco usage. Approximately, how long have you used chewing tobacco? If you have used chewing tobacco for several periods, and quit in between, we ask you to please state the total time you have used chewing tobacco. For example if you used chewing tobacco for 5 years, quit for 1 year, and have used chewing tobacco for the past 2 years - please indicate 7 years.

## HIGHLIGHTS

- Most US smokers with low quit intention tried snus when offered it for free
- After 3–4 months, most of these smokers stopped regular snus use
- Frequency and quantity of snus use among current users were consistently low
- Male gender and initial expectations about snus use predicted snus use outcomes

## ABSTRACT

To refine public health policy amidst a changing landscape of tobacco products in the United States, it is first necessary to describe fully the nature of smokers' alternative product use. Little research addresses smokers' snus use, and most studies are limited by small samples, cross sectional designs, and crude outcome measurement. This study sample includes 626 adult US smokers who denied intention to quit in the next month and were randomized to receive free snus during a 6 week sampling period, after which no snus was provided. Participants were then followed for one year. Outcome data were collected via phone. Participants (mean age: 48.7 years) were predominately female, White non-Hispanic. Eighty-four percent reported trial of snus. Eleven percent reported purchase (i.e., adoption). Current use declined from 47.1% at the end of the sampling period to 6.5% at the end of follow-up. Frequency and quantity of snus use among current users was low. Among snus users, 79.3% said it functioned as an alternative to smoking and 58.4% said it provided a means of coping with smoking restrictions; options not mutually exclusive. In logistic regressions, men were more likely to report trial (odds ratio [OR] = 2.33,  $p < 0.01$ ) and adoption (OR = 1.84,  $p < 0.05$ ) than women. Baseline expectations about the nature of snus use also predicted snus outcomes (OR = 1.28–1.78,  $p < 0.05$ ). Smokers showed willingness to try snus, but product interest waned over time. Snus as currently marketed is unlikely to play a prominent role in US tobacco control efforts.

## 1. Introduction

Conventional smokeless tobacco (chew tobacco and snuff) use has historically been low among United States (US) adults (Bhattacharyya, 2012; Fix et al., 2014; Mumford, Levy, Gitchell, & Blackman, 2006).

Data from the 2000–2010 National Health Interview Surveys, for example, indicate only 1–2% of US adults are “regular” smokeless tobacco users (Bhattacharyya, 2012). Recently, however, the tobacco industry's investment in smokeless tobacco increased (Federal Trade Commission, 2011; Mejia & Ling, 2010; Richardson, Ganz, Stalgaitis, Abrams, & Vallone, 2014), likely in response to an expansion of smoke-free legislation and a shift in social norms that stigmatizes smoking (Bayer & Stuber, 2006). Options for smokeless tobacco products changed with the introduction of low nitrosamine smokeless tobacco (LNST) products such as snus, an oral, spitless, pouched, and flavored tobacco. Comparative carcinogenic profiles suggest snus is

Gray), [garrettm@muscc.edu](mailto:garrettm@muscc.edu) (E. Garrett-Mayer), [carpente@muscc.edu](mailto:carpente@muscc.edu) (M.J. Carpenter).

less harmful than conventional tobacco products (Hatsukami, Lemmonds, Zhang, et al., 2004; Stepanov, Jensen, Hatsukami, & Hecht, 2008), including cigarettes (Lee, 2011; Levy et al., 2006; O'Connor, 2012), but it still carries health risks. The introduction of snus to the US tobacco market has not yet changed the nationwide prevalence of smokeless tobacco use (Agaku et al., 2014; Bhattacharyya, 2012; Biener et al., 2016; Boyle, Saint Claire, Kinney, D'Silva, & Carusi, 2012; Choi & Forster, 2013; Fix et al., 2014; Lee, Hebert, Nonnemaker, & Kim, 2014; Maher, Bushore, Rohde, Dent, & Peterson, 2012; Soneji, Sargent, & Tanski, 2016; Zhu et al., 2013, 2009), but there may exist subgroups of the population who are more receptive to snus than others.

Tobacco industry internal documents, marketing strategies, and advertisements all pinpoint current smokers as the intended consumer of snus (Bahreinifar, Sheon, & Ling, 2013; Mejia & Ling, 2010; Rogers, Biener, & Clark, 2010; Timberlake, Pechmann, Tran, & Au, 2011). Smokers might have interest in snus due to the: 1) perception that snus is less harmful than cigarettes (Biener & Bogen, 2009; Choi, Fabian, Mottey, Corbett, & Forster, 2012; Lund, 2012), 2) desire to circumvent smoking restrictions and temporarily mitigate nicotine withdrawal (Bahreinifar et al., 2013; Biener et al., 2016; Wray, Jupka, Berman, Zellin, & Vijayakumar, 2012), and/or 3) intention to use snus as a means of smoking reduction or cessation (Biener et al., 2016; Choi et al., 2012; Lund, 2012). Thus, snus use could function as an alternative to smoking, a complement to smoking, or both. Indeed, one of the more reliable predictors of snus (and other LNST) use is smoking status: current and former smokers are more likely to report snus use than never smokers (Biener et al., 2016; Choi & Forster, 2013; Zhu et al., 2013).

Very few population based studies of snus use among US adult smokers exist (Biener et al., 2016; Boyle et al., 2012; Lee et al., 2014; Rath, Villanti, Abrams, & Vallone, 2012). Prior work primarily aims to determine the pervasiveness of “dual use,” and results indicate a 30 day point prevalence of snus use occurs in 3–10% of current smokers (Biener et al., 2016; Boyle et al., 2012). This literature offers insights into smokers' willingness to try snus, but is constrained by limited outcome measurement and the fact that most studies are cross sectional. This report aims to advance the current literature via a detailed description of snus uptake during a longitudinal study with adult US smokers who denied intention to stop smoking in the near future.

## 2. Material and methods

### 2.1. Study overview

Adult smokers ( $N = 1236$ ) throughout the US who denied intention to quit in the next 30 days were recruited into a clinical trial and randomized to receive or not receive free snus during a 6 week sampling period ([clinicaltrials.gov](http://clinicaltrials.gov): NCT01509586). After this period, participants were advised to quit all tobacco use and then followed for one year. This report focuses on the snus group ( $n = 626$ ). The tobacco industry did not support this study in any way. Study procedures began after approval from the Medical University of South Carolina's institutional review board.

### 2.2. Eligibility criteria

Participants met these criteria based on their self report: 1) age  $\geq 19$  years; 2) English speaking; 3) residency in the contiguous US; 4) not currently pregnant, breastfeeding, or planning to become pregnant in the near future; 5) no cardiovascular event in the past six months; 6) no smokeless tobacco use in the past six months; 7) daily smoker of  $\geq 10$  cigarettes per day; 8) no smoking cessation medication use in the past three months; 9) no quit attempt lasting  $> 1$  week in the past six months; and 10) low motivation to quit smoking, operationalized as  $\leq 7$  on a 0 to 10 contemplation ladder (Biener & Abrams, 1991) and no stated intention to quit in the next 30 days based on stage of change assessment (Prochaska & Velicer, 1997). The tobacco specific

eligibility criteria ensured recruitment of regular smokers who were “unmotivated” to quit and relatively snus naïve.

### 2.3. Snus

Snus participants were offered Camel Snus (Reynolds American, Inc.), a spitless, pouched moist snuff, available in either Winterchill or Robust, both 2.5–2.8 mg nicotine per pouch (Hatsukami et al., 2015; Stepanov et al., 2012). Early testing suggested Camel Snus offers greater nicotine delivery and withdrawal/craving relief than other LNST (Hatsukami et al., 2011; Stepanov et al., 2012, 2008). Twice during the sampling period, participants were offered free samples of Camel Snus. For those who accepted this offer, up to 20 tins (300 total pouches) were mailed over four shipments.

### 2.4. Procedures

Knowledge Networks, which maintains national market research panels, emailed a study invitation to potential participants that contained a link to a brief study description. Interested individuals then completed an online eligibility screener. A more complete study description was provided to eligible individuals, with mention of a “new, potentially safer tobacco product” and assurances that study participation required neither use of this product nor smoking cessation. Names and contact information for eligible, interested individuals were forwarded to study staff. Enrollment in this study (November 2011–August 2013) was formalized upon attainment of written informed consent and completion of a baseline assessment via a combination of mail questionnaire and phone interview.

Participants learned their group assignment during the initial call. Snus participants received information about Camel Snus, including 1) how to use it; 2) reasons for its classification as a LNST product; and 3) cautions about product safety. Between Week 0 (post baseline assessment) and Week 6 (after which snus was no longer offered), participants received three equally spaced calls. At each call, emphasis was placed on self-determination of snus use. After the 6 week sampling period, participants were given brief advice to quit all tobacco use and their state Quitline's contact information; this occurred at the Week 6 call only. Six additional calls spanned the 1 year follow up period. Of the 5634 scheduled calls ( $626 \times 9$ ), 85.7% were completed. Participants were reimbursed for each complete assessment (US \$130 maximum).

### 2.5. Measures

#### 2.5.1. Baseline

This assessment included questions about participants' demographic and tobacco use history, including the *Heaviness of Smoking Index* as a measure of nicotine dependence (Heatherton, Kozlowski, Frecker, Rickert, & Robinson, 1989). Participants also rated their concern about the personal health effects of smoking (“very or somewhat” versus “only slightly or not”), motivation to quit smoking next month (0 = very definitely no to 10 = very definitely yes), and confidence about quitting smoking next month (0 = not at all confident to 10 = extremely confident). Perceived personal harm from LNST (exclusive of electronic cigarettes) was measured on a 0 = not at all harmful to 10 = very much harmful scale. Finally, expectations about the likelihood of using LNST for various purposes (e.g., reduce smoking) were measured on a 0 = not at all likely to 3 = very likely scale.

#### 2.5.2. Tobacco use outcomes

At each follow up assessment (Week 0 to 58), participants provided information via timeline follow back procedures. Frequency (number of days) and quantity (number of units per day) of use in the past week was measured separately for cigarettes and snus, allowing determination of current users based on 7 day point prevalence. Additionally, participants were asked about the occurrence of any snus use since the last

assessment, allowing determination of continuous abstinence. Any purchase of snus since the last assessment was also ascertained. Any report of snus use triggered questions as to whether or not snus was used 1) as an alternative to smoking, i.e., a participant could smoke, but chose not to and/or 2) as a means of coping with smoking restrictions.

## 2.6. Statistical analysis

Descriptive statistics were used to describe participants and all study variables. No missing data were imputed to avoid assumptions regarding the occurrence of snus use. Consequently, the effective sample size varies across analyses. Binary snus outcomes include: 1) any use, 2) any frequent use (use on 6–7 days in a given week), and 3) any purchase, all based on the entire study period. Independent samples *t* tests and chi square tests were conducted to identify potential predictors of snus outcomes. All baseline variables were considered as predictors, and all predictors demonstrating a significant ( $p < 0.05$ ) univariate relationship with a given outcome were entered simultaneously into a multivariate binomial logistic regression model for that outcome.

## 3. Results

### 3.1. Participants

Table A shows the demographic characteristics and tobacco use history of snus participants ( $n = 626$ ). This predominantly female, White non-Hispanic group had a mean of 48.7 years of age. Roughly half were in a relationship, received more than a high school education, and were employed. Participants had a longstanding history of daily smoking and moderate nicotine dependence. Most had a history of making a quit attempt, but few had done so in the past year. Home smoking restrictions were common. Most participants endorsed concern about the effects of smoking on their health. By design, both motivation to quit and confidence about quitting were low. Finally, participants were generally familiar with LNST, though use of these products was rare.

**Table A**  
Participants' demographic and tobacco use history at baseline ( $n = 626$ ).

Variable	Percent	<i>M</i> ( <i>SD</i> )
Demographic		
Age, years		48.7 (12.5)
Male	30.0	
White non-Hispanic	85.5	
Married or partnered	47.2

Employed full- or part-time	41.8	
Tobacco use history		
Nicotine dependence, heaviness of smoking index		3.5 (1.2)
Age at onset of daily smoking, years		16.9 (3.7)
Cigarettes per day in a typical week		20.1 (8.7)
24-hour smoking quit attempt, lifetime	77.2	
24-hour smoking quit attempt, past year	9.3	
Smoking restrictions in home	44.7	
Somewhat/very concerned about personal harm from smoking	73.7	
Motivation to quit smoking <sup>a</sup>		1.4 (2.3)
Confidence about quitting smoking <sup>b</sup>		2.6 (3.1)
Heard of any LNST products	76.0	
Use of any LNST products, lifetime	6.9	
Perceived personal harm from LNST <sup>c</sup>		5.7 (2.8)
Likelihood of LNST use to reduce smoking <sup>d</sup>		1.6 (1.1)
Likelihood of LNST use to quit smoking <sup>d</sup>		1.3 (1.1)
Likelihood of LNST use to cope with smoking restrictions <sup>d</sup>		1.6 (1.2)

<sup>a</sup> 0 to 10 scale where 0 = *very definitely no* and 10 = *very definitely yes*.

<sup>b</sup> 0 to 10 scale where 0 = *not at all confident* and 10 = *extremely confident*.

<sup>c</sup> 0 to 10 scale where 0 = *not at all harmful* and 10 = *very much harmful*.

<sup>d</sup> 0 to 3 scale where 0 = *not at all likely* and 3 = *very likely*.

### 3.2. Snus use: trial, amount, and adoption

Eighty-four percent of participants reported at least one occasion of snus use (i.e., trial) on the basis of completer analyses ( $n = 366$  with complete data through Week 58). Across the entire study, 20.9% of participants reported at least one occasion of frequent snus use. Both the percentage of current users and frequent users declined between Week 6 (47.1% and 17.6%, respectively) and Week 58 (6.5% and 1.9%, respectively). The percentage of never, past, or current users at select weeks is shown in Fig. A.

The frequency and quantity of snus use among current users appeared stable across time. Average amount of use at select time points is based on the report of current users only: Week 6 ( $n = 265$ ), Week 10 ( $n = 175$ ), Week 32 ( $n = 49$ ), and Week 58 ( $n = 22$ ). Days of use in the past week ( $M \pm SD$ ) was as follows for Week 6, 10, 32, and 58:  $4.0 \pm 2.4$ ,  $4.3 \pm 2.4$ ,  $3.8 \pm 2.3$ , and  $3.2 \pm 2.2$ , respectively. Amount of use on using days in the past week ( $M \pm SD$ ) was as follows for Week 6, 10, 32, and 58:  $2.9 \pm 2.1$ ,  $2.8 \pm 1.7$ ,  $2.5 \pm 1.0$ , and  $2.2 \pm 1.2$ , respectively.

Adoption of snus, defined as purchase, occurred in 11.0% ( $n = 69/626$ ) of participants, a figure that rises to 13.1% ( $n = 69/525$ ) if based on those who tried snus. Repeat purchase was low: 4.5% ( $n = 28/626$ ) among all snus participants, 5.3% ( $n = 28/525$ ) among those who tried snus, and 40.6% ( $n = 28/69$ ) among those who made an initial purchase.

### 3.3. Purpose of snus use

Among participants who reported current snus use and answered follow-up questions about its purpose ( $n = 469/474$ ), 79.3% ( $n = 372/469$ ) said snus use functioned at least once as an alternative to smoking and 58.4% ( $n = 277/474$ ) said it functioned at least once as a method of coping with smoking restrictions. Roughly half of these respondents endorsed snus use for both purposes (45.2%;  $n = 210/465$ ) while a minority denied snus use for either purpose (7.1%,  $n = 33/465$ ). Among those who used snus for a singular purpose ( $n = 222/465$ ), it was more likely to be used as an alternative to smoking (71.6%,  $n = 159/222$ ) than as a means of coping with smoking restrictions (28.4%,  $n = 63/222$ ).

### 3.4. Prediction of snus outcomes

In univariate analyses, ten of 21 variables emerged as significant predictors of  $\geq 1$  snus outcomes (data not shown). Consequently, the binary logistic regression models for snus trial, frequent use, and adoption included a combination of 10 predictors (Table B). Consistent predictors across outcomes were gender and certain expectations about LNST use. First, male gender increased the odds of trial (odds ratio [OR] = 2.33), frequent use (OR = 2.58), and adoption (OR = 1.84). Second, a higher perceived likelihood of using LNST to reduce smoking increased the odds of trial (OR = 1.78) and frequent use (OR = 1.45). Finally, a higher perceived likelihood of LNST use to cope with smoking restrictions increased the odds of frequent use (OR = 1.28).

### 3.5. Dual use of snus and cigarettes

In most cases, participants' snus use was concurrent with continued smoking. Fig. B shows the prevalence of dual use, defined as a positive 7-day point prevalence of snus and cigarette use, throughout the study. Snus use without smoking occurred in <1.0% ( $n = 1$ ) of participants. Far more common was dual use (4.2–47.5% across time) or smoking in isolation (51.7–87.3% across time), with dual use decreasing over time.

**Fig. A.** Participants' snus use status over time ( $n = 366$ – $376$ ). *Note.* Snus use categories are defined as follows: 1) Never user: no snus use at any point throughout the entire study, 2) Past user: snus use on at least one occasion, but no use during the 7 days prior to the assessment, 3) Current infrequent user: snus use on 1–5 of the 7 days prior to the assessment, and 4) Current frequent user: snus use on 6–7 of the 7 days prior to the assessment. Categories are based on completer analysis, i.e., participants with no missing snus data at any time-point.

#### 4. Discussion

The tobacco industry uses direct mail marketing (i.e., advertisements, coupons, promotional products, and offers for free samples) to encourage smokers' experimentation with snus (Bahreinifar et al., 2013; Biener et al., 2016; Brock, Schillo, & Moilanen, 2015). To create a naturalistic setting in which to observe snus trial and adoption among a nationwide sample of "unmotivated" adult smokers in the US, this study mimicked the tobacco industry's direct to consumer approach by delivering snus samples via mail. Snus was provided free of charge for ad libitum use, and there was minimal tobacco cessation treatment delivery. This novel methodological approach to the study of alternative tobacco products optimizes the ecological validity of study findings, as it created a situation in which snus use was neither contrived nor mandated as part of study participation. This longitudinal study describes in detail the nature of snus uptake among a large group of US smokers, and it represents a necessary first step toward refinement of tobacco control policy amidst a changing landscape of tobacco products.

Participants showed willingness to try snus, but their interest in this product waned significantly over time. The prevalence of current users changed from 47.1% at the end of the 6 week sampling period to 6.5% a year later, an 86.2% reduction. Frequent use, which was prevalent in 20.9% of participants, mainly occurred in the early months of the study. Furthermore, amount of snus use was low throughout the study. Interpretation of these data, though, must account for the fact that dual use of cigarettes and snus was the norm. Most US population based reports of snus use describe cross sectional studies and categorize participants as "never," "former," or "current" users and/or categorize frequency of use as "every day," "some days," "rarely," or "not at all" (Agaku et al., 2014; Biener et al., 2016; Boyle et al., 2012; Choi & Forster, 2013; Lee et al., 2014; Rath, Villanti, Abrams, & Vallone, 2012; Soneji et al., 2016), making it difficult to compare our findings with prior studies. Two other US sampling studies ( $n$ 's < 200) provide some help in this regard, as both found an average snus use of approximately 3 pouches/day during a 5–7 day period of concomitant smoking (Krautter, Chen, & Borgerding, 2015; O'Connor et al., 2011). The

**Fig. B.** Participants' 7-day point prevalence of cigarette and/or snus use by time ( $n = 492$ –551). Note. Snus use alone occurred in <1% of participants at each assessment, so those data are not depicted.

quantity of snus use reported here is consistent with these studies. Nonetheless, future studies need to replicate these findings, and would be strengthened by technological approaches that allow fine grained, real time tobacco use assessment (Dallery, Kurti, & Martner, 2015).

This study adds to the LNST literature by exploring adoption of snus use as a new, potentially long term tobacco use behavior. Many health behavior change models and applications consider adoption of a new behavior as a function of time (e.g., maintenance of X behavior six months post intervention) (Hughes, Keely, & Naud, 2004; Prochaska & Velicer, 1997; Williams, Niemiec, Patrick, Ryan, & Deci, 2009; Ziegelmann, Lippke, & Schwarzer, 2006), but it was operationalized here in strictly behavioral terms. Due to the nature of the eligibility criteria and no knowledge of a pouch to cigarette conversion rate, full/partial substitution was ruled out as the criterion for adoption. This led us to define adoption as purchase, consistent with marketing and business models (Gourville, 2003). With 11.0% of participants reporting purchase, we report a low rate of adoption, with one caveat: snus was possibly over supplied. For current users at any given time, frequency of use was basically every other day and amount of use was 2–3 pouches per using day. These data, in combination with a reduction in the prevalence of current users over time, suggest the amount of snus we made available probably exceeded participants' needs (see O'Connor et al., 2011 for a similar result). Consequently, our criterion for adoption has its shortcomings.

Most advertisements highlight snus' utility in situations where smoking is prohibited (indirectly marketing dual use of cigarettes and snus) (Timberlake et al., 2011), but some promote switching from cigarettes to snus (indirectly marketing snus as a means of smoking cessation) ("Camel Snus [advertisement], 2011"). As advertised, many participants said snus served multiple purposes, including as a means of coping with smoking restrictions and an alternative to smoking. The latter purpose does not necessarily reflect intent to switch products, but it does support smokers' willingness to try snus as a temporary replacement for the far more established behavior of smoking (O'Connor et al., 2011). Baseline expectations about snus use for a specific purpose predicted trial and frequent use in this study, supporting the theoretical link between intention and behavior (Ajzen, 1991; Rogers, 1983; Triandis, 1977). The intention behind snus use is important, especially since another randomized clinical trial

with "unmotivated" smokers found change in smoking dependent upon the prescribed nature of snus use during a 2 week sampling period (Burris, Carpenter, Wahlquist, Cummings, & Gray, 2014). Specifically, individuals instructed to use snus as a means of coping with smoking restrictions reported a reduction in cigarettes per day that was far lower than that reported by those instructed to use snus as a means of smoking reduction (Burris, Carpenter, Wahlquist, Cummings, & Gray, 2014). Furthermore, among smokers who report readiness to quit, snus use shows some efficacy for smoking cessation in randomized clinical trials (Fagerstrom, Rutqvist, & Hughes, 2012; Hatsukami et al., 2015; Joksić, Spasojević Tišma, Antić, Nilsson, & Rutqvist, 2011; Tønnesen, Mikkelsen, & Bremann, 2008). Consequently, if the tobacco control community chooses to advocate for snus as a means of harm reduction a topic which is still up for debate (Hatsukami, Ebbert, Feuer, Stepanov, & Hecht, 2007; Hatsukami, Lemmonds, & Tomar, 2004; Levy et al., 2006; O'Connor, 2012; Tomar, 2007) then messaging around the purpose of snus use must be clear.

The aforementioned study findings must be considered in light of study limitations. First, a single snus product was offered. At the outset of this study, Camel Snus was one of the most aggressively marketed and widely available LNST products in the US (Bahreinifar et al., 2013; Delnevo et al., 2014; Rogers et al., 2010), and laboratory studies suggested consumers preferred it over other LNST products (Hatsukami et al., 2011; Stepanov et al., 2012, 2008). While Camel Snus was selected for this study because it appeared to be the most appealing LNST product to smokers, it is possible features of this product influenced study outcomes. Second, the study population consisted of smokers who reported little to no interest in smoking cessation. This was due to concern about the ethical implications of providing tobacco to treatment seeking smokers along with the desire to capture snus use among the group of smokers who are most widely represented in the US/Canadian population (i.e., smokers without intention to quit in the near future) (Centers for Disease Control and Prevention, 2011; Cunningham, Kushnir, & McCambridge, 2016; Wewers, Stillman, Hartman, & Shopland, 2003). Nonetheless, some research shows snus use is positively associated with indicators of motivation to quit smoking, including a recent quit attempt (Kalkhoran, Grana, Neilands, & Ling, 2015; Schauer, Pederson, & Malarcher, 2016; Zhu et al., 2013). Given this, the generalizability of this study is limited to "unmotivated" smokers, a group one might expect to have a lower likelihood of snus use than

smokers who are ready to quit smoking and view snus as a quit aid. Finally, White, non Hispanics and females are both over represented in this US sample (United States Census Bureau, 2015).

#### 4.1. Conclusions

This study found that when “unmotivated” smokers are offered free snus for a finite period of time, most will try it, but only a fraction will become regular snus users, and most of these individuals will stop snus use altogether after a few months. The removal of any start up costs for snus use, including cost for the product itself and cost related to travel to obtain said product, helped ensure study outcomes were not a function of access. Consequently, there likely exist aspects of the product, the consumer, and/or the environment that limit snus uptake in this population. The results of surveys, focus groups, and lab studies point toward dislike of the taste, oral sensation, and packaging of snus (Bahreinifar et al., 2013; Biener et al., 2016), in addition to dissatisfaction with nicotine delivery and suppression of withdrawal/craving (Blank & Eissenberg, 2010; Hatsukami et al., 2015), as reasons for smokers' discontinuation of snus use. Additionally, some smokers' perception of themselves as a “smoker” and not a “snuser” or “dual user” may reduce the likelihood of regular snus use (Bahreinifar et al., 2013). Finally, the initial appeal of snus (and its inherent smokeless quality) may subside as tobacco control shifts from smoke free legislation to tobacco free legislation. Taken together, the current evidence indicates that snus as currently marketed is unlikely to play a prominent role either positive or negative in tobacco control efforts in the US.

#### Role of funding sources

This work was supported the National Cancer Institute at the National Institutes of Health (grant numbers R01 CA154992 to M.J.C., K07 CA181351 to J.L.B., and P30 CA138313 to A.J.A.); and the National Center for Advancing Translational Science at the National Institutes of Health (grant number UL1 TR000062). The content is solely the responsibility of the authors and does not necessarily represent the official views of the funding agencies. The funding agencies had no role in study design, data collection, analysis, or interpretation, manuscript preparation, or the decision to submit this manuscript for publication.

#### Contributors

Carpenter was the principal investigator and took the lead in study design. Burris led data analysis and interpretation for this study in addition to being principally responsible for writing this manuscript. All authors contributed to the preparation of this manuscript, including editing, and approved the final manuscript.

#### Conflict of interest

Alberg, Burris, Carpenter, Garrett-Mayer, Gray, and Wahlquist have no conflict of interest to declare. Cummings has received grant funding from Pfizer, Inc. to study the impact of hospital-based tobacco cessation treatment. Cummings also receives funding as an expert witness in litigation filed against the tobacco industry.

#### Acknowledgments

The authors would like to acknowledge the work of all research assistants who contributed to the conduct of this study, including but not limited to Amy Boatright, Nichols Mabry, Easha Tiwari, and Caitlyn Hood.

**Keywords:** Smokeless tobacco products, bacterial populations, microbial diversity,  
*Bacillus* species

**26 ABSTRACT**

27 There are an estimated 8-million users of smokeless tobacco products (STPs) in the United  
28 States, yet limited data on microbial populations within these products exist. To better  
29 understand the potential microbiological risks associated with STP use, a study was conducted  
30 to provide a baseline microbiological profile of STPs. A total of 90 samples, representing 15  
31 common STPs, were purchased in Little Rock, AR, and Washington, DC, metropolitan areas in  
32 November 2012, March 2013, and July 2013. Bacterial populations were evaluated using  
33 culture, pyrosequencing and denaturing gradient gel electrophoresis (DGGE). Moist snuff  
34 products exhibited higher levels of bacteria (average  $1.05 \times 10^6$  CFU/g STP) and diversity of  
35 bacterial populations than snus (average  $8.33 \times 10^1$  CFU/g STP) and some chewing tobacco  
36 products (average  $2.54 \times 10^5$  CFU/g STP). The most common species identified by culturing  
37 were *Bacillus pumilus*, *B. licheniformis*, *B. safensis* and *B. subtilis*, followed by members of the  
38 genera *Oceanobacillus*, *Staphylococcus* and *Tetragenococcus*. Pyrosequence analyses of the  
39 16S rRNA genes identified the genera *Tetragenococcus*, *Carnobacterium*, *Lactobacillus*,  
40 *Geobacillus*, *Bacillus*, and *Staphylococcus* as the predominant taxa. Several species identified  
41 are of possible concern due to their potential to cause opportunistic infections and reported  
42 abilities to reduce nitrates to nitrites, which may be an important step in the formation of  
43 carcinogenic tobacco-specific N'-nitrosamines. This study provides a microbiological baseline  
44 to help fill knowledge gaps associated with microbiological risks of STPs and to inform potential  
45 regulations regarding manufacture and testing of STPs.

**47 IMPORTANCE:**

48 It is estimated that there 8-million users of smokeless tobacco products (STPs) in the United  
49 States, however there are limited data on microbial populations that exist within these  
50 products. The current study was undertaken to better understand the potential microbiological  
51 risks associated with STP use and provide a baseline microbiological profile of STPs. Several  
52 bacterial species were identified that are of possible concern due to their potential to cause  
53 opportunistic infections. In addition some species have abilities to reduce nitrates to nitrites,  
54 which may be an important step in the formation of carcinogenic tobacco-specific N'-

55 nitrosamines. Overall, this study provides a microbiological baseline to help fill knowledge  
56 gaps related to the microbiological risks of STPs and to inform potential regulations regarding  
57 manufacture and testing of STPs.

58

## 59 INTRODUCTION:

60 The use of tobacco products is a major health concern throughout the world. It is  
61 estimated that 3.5% of US adults and 6.1% of high school students are users of smokeless  
62 tobacco products (STPs) (1, 2). As with many consumer products, there is the potential for the  
63 presence of microorganisms in tobacco products that may be of human health concern (3).  
64 Very limited data on the microbial populations present in STPs are available and the data that  
65 are publicly available are mostly more than 20 years old (4). Tobacco processing and STP  
66 manufacturing methods can greatly affect the microbial content of STPs (5). Thus, there is a  
67 strong need to gain an understanding of the types and numbers of microorganisms that may be  
68 present in commercially available STPs for the protection of public health.

69 Smokeless tobacco products have been considered by some consumers to be a “less  
70 risky” alternative to smoking cigarettes (6), even though the use of STPs has been linked with  
71 an increased risk for the development of oral, pancreatic and esophageal cancers. There are  
72 multiple types of STPs sold in the United States, including snuff, snus, chewing tobacco, and  
73 some forms of dissolvable tobacco (6, 7). Snuff is a finely ground tobacco product that is sold as  
74 loose, moist or dry, or packaged in a pouch (Figure 1). Moist snuff represents over 75% of the  
75 STP market share in the United States (8). Loose snuff users typically place a pinch (dip) of the  
76 tobacco product between their gum and lip, where the tobacco compounds are absorbed  
77 through the oral mucosa. Loose leaf chewing tobacco, which has a much larger particle (cut)  
78 size, is also placed between the gum and lip and the users of both types of products typically  
79 spit out saliva that is generated during tobacco usage. In contrast, snus, which is typically a  
80 very fine, dry tobacco purchased in a pouch, does not induce the need to spit. Other STPs  
81 include newer dissolvable products derived from tobacco, such as orbs, strips and sticks, which  
82 are ingested during use (6). As the name implies, STPs are consumed without smoking  
83 (heating), which could lead to greater potential for the consumer to be exposed to viable

microorganisms or their toxic metabolites during use, if the product is contaminated or the manufacturing process fails to reduce the microorganisms commonly found in tobacco to lower levels.

Few studies have been undertaken to address the types or quantities of microorganisms and their byproducts (e.g., proteins, lipids, DNA and cell walls) in tobacco products. The studies that have been undertaken are primarily focused on cigarette products and were mostly done before the 1990s (9). More recent studies that have focused on cigarettes using modern molecular methods have reported the detection of a wide diversity of bacterial genera, including Gram-positive organisms (*Bacillus*, *Clostridium*, *Enterococcus* and *Staphylococcus*) and Gram-negative organisms (*Acinetobacter*, *Burkholderia*, *Campylobacter*, *Klebsiella* and *Pseudomonas*) (3). Many of these genera include species that have been associated with human diseases and may be present in STPs. A case report and follow-up study from the 1950s indicated that snuff was the likely source of *Pseudomonas aeruginosa* in a patient who developed chronic bronchitis (10). In the follow-up investigation into the source of the *P. aeruginosa*, the medical team sampled multiple previously unopened packages of snuff and found a wide range of potential bacterial pathogens, including *Staphylococcus aureus*, *S. epidermidis*, *Bacillus subtilis*, *Proteus vulgaris* and *P. aeruginosa* (10). In 2002, Rubinstein and Pedersen isolated five different *Bacillus* species from chewing tobacco sold in the US (11). Two of the species detected, *B. licheniformis* and *B. pumilus*, have been associated with pulmonary inflammation and opportunistic infections. Culture supernatants from these bacilli caused tissue edema and dysfunction when inoculated into the oral cavity of hamsters (11). *B. pumilus* and *B. subtilis* have also been identified as causative agents in spice-associated outbreaks and may produce a mild toxin after growing to a large population in a food that can result in illness (12, 13).

Many of the previous microbial characterization studies looked at relatively small sample sets, primarily from cigarettes, and did not analyze the types or quantities of microorganisms in STPs. Thus, there are data gaps in understanding the microorganisms present in the STPs, which are potentially important to public health for the prevention of infectious diseases (9). Therefore, the goal of this study was to conduct a microbiological

113 survey of STPs, which should help to fill scientific knowledge gaps associated with  
114 microbiological risks of currently marketed STPs that are important during FDA's tobacco  
115 product reviews and help to create a microbiological baseline for science-based regulation of  
116 tobacco product manufacturing and testing.

117

## 118 **MATERIALS AND METHODS:**

### 119 **Sample Collection**

120 Fifteen smokeless tobacco products (STPs) were purchased from retail locations in the Little  
121 Rock, AR and Washington, DC, metropolitan areas in November 2012, March 2013 and July  
122 2013. The same brands and products were collected at each time and location (Table 1). For  
123 each of the 90 total product samples collected, information on the manufacturer, lot, purchase  
124 location, date of purchase, and sell-by date (if available) were recorded. The STPs were  
125 purchased and placed unopened in zip top bags; the Little Rock, AR, samples were hand carried  
126 and those from Washington, DC, were shipped by a common carrier to the laboratory in  
127 Jefferson, AR to conduct the experimental analyses. The unopened packages were stored at  
128 room temperature, as they were in the retail setting, until processing. Prior to sampling, the  
129 STP packages were placed under ultraviolet light in a biological safety cabinet for at least 30  
130 minutes to decontaminate the exterior packaging and minimize potential contamination by  
131 exterior microorganisms. The date when the package was initially opened for sample analyses  
132 was considered day 1.

133

### 134 **Sample Characterization**

135 **Moisture Content.** The tobacco products were tested for pH and moisture content after  
136 appropriate equilibration at room temperature. The moisture content was determined using  
137 the Karl Fischer Coulometric Titration method with samples prepared as described by ISO 6488  
138 (14). Samples were prepared by adding a 0.5 g sample of the tobacco product to 25 ml of  
139 methanol in a desiccated Erlenmeyer flask and the flask was sealed with Parafilm M® and  
140 shaken for 30 min at room temperature. After shaking, the tobacco samples were left at room  
141 temperature for 24 hours to allow for moisture extraction from the samples. A 1.0 g aliquot

142 was transferred to a Karl Fischer titration apparatus for sample analysis and the water content  
143 (mg water/g sample) was calculated. Each of the samples was analyzed a minimum of two  
144 times.

145 **pH Determination.** The pH was determined by weighing 1.0 g of tobacco and adding it to a 50-  
146 mL polypropylene container with 10 mL of deionized distilled water. The samples were stirred  
147 and the pH of the solution measured over a 15-min time interval to get a stable pH value.

148 **Particle Size Determination.** The particle size was evaluated for each product during the first  
149 sampling period by measuring the length and width to the nearest mm. A total of 100  
150 individual particles were measured; their dimensions recorded; and the mode particle size  
151 range was determined for each product. In the second and third sampling periods, the  
152 products were compared to the results of the first period to verify that the products had the  
153 same particle sizes.

154 **Microbial Loads.** A 0.1 g tobacco sample was weighed out aseptically and placed in a sterile  
155 tube, to which 10 ml of sterile water was added. The samples were thoroughly mixed by  
156 vortexing. Total aerobic plate counts were determined for each product during the second and  
157 third samplings by spreading 100  $\mu$ l of serially diluted tobacco suspension onto sheep's blood  
158 agar (SBA) plates and incubating the plates overnight at 37°C. After incubation, the colonies  
159 that grew on the plates were counted. For each sample, the suspensions were plated in  
160 triplicate and the numbers of aerobic bacteria present in the samples were determined by  
161 multiplying the number of organisms counted times the dilution factor. To assess the  
162 differences in microbial loads associated with different products, data from the four samples  
163 analyzed for each product were combined and assessed using the Kruskal-Wallis One Way  
164 Analysis of Variance on Ranks approach using the SigmaPlot program (version 13.0, Systat  
165 Software, Inc. Chicago, IL). Significant difference between the microbial loads of products was  
166 defined as  $p < 0.05$ .

167 **Sample Recovery Experiments.** To determine whether there were likely inhibitory substances  
168 or product conditions in tobacco products that limited the ability of microorganisms to grow,  
169 three representative STP types (Brand C Wintergreen Moist Snuff, Brand H Chewing Tobacco  
170 and Brand F Snus Mint) were evaluated by bacterial seeding and recovery experiments. With

171 the exception of a subset of Brand F Snus Mint samples, the STP samples were autoclaved to kill  
172 the resident microbial populations and inoculated with sterile phosphate buffered saline (PBS)  
173 or approximately  $10^3$  colony forming units (CFU)/ml of *S. aureus*, *P. aeruginosa* or *B. subtilis* as  
174 described previously (15). After a two-hour incubation, 3 ml of PBS was added to the STPs and  
175 100  $\mu$ l aliquots were plated on tryptic soy agar plates and incubated overnight at 37°C. The  
176 following day the plates were counted and results compared to those of the other STP samples  
177 and the initial cell suspensions that were diluted and plated. For each experiment, the samples  
178 were plated in triplicate and the experiments repeated at least twice. The recovery efficiency  
179 was calculated by dividing the average number of organisms recovered from the samples  
180 divided by the average CFU counted for the initial inoculum. To assess the differences in  
181 recovery, the Kruskal-Wallis One Way Analysis of Variance on Ranks approach was employed  
182 using SigmaPlot. Significant difference was defined as  $p < 0.05$ .

183

#### 184 **Detection of Culturable Bacteria**

185 **Culturing.** The viable and culturable bacteria were identified by growth on three different  
186 media. Culturing of bacteria was done on the day of initial sampling (day 1) and subsequently  
187 on days 3, 5, 8, and 15. Between samplings, the STPs were stored at 25°C in ambient conditions.  
188 For culturing, 100- $\mu$ l aliquots of the tobacco suspension (prepared as described above) were  
189 transferred to: a) SBA, b) mannitol salt agar (MSA), and c) MacConkey agar plates (MAC). For  
190 the initial sampling, the plates were incubated at 25, 37, and 42°C and observed for growth (11).  
191 Because there were no distinguishable differences of colonies growing at the different  
192 temperatures, the 37°C incubation temperature was used for subsequent cultures. Visually  
193 unique bacterial colonies were selected and described; representative colonies were sub-  
194 cultured, identified (as described below), and archived in BHI broth with 20% glycerol at -80°C  
195 for long term storage.

196 **Bacterial Identification.** Bacterial colonies were picked from the subculture plates and added to  
197 sterile water in PCR tubes or 96-well plates and thoroughly mixed. The suspensions were  
198 heated to 99°C for 10 min to lyse the bacterial cells and liberate the DNA template for  
199 amplification and sequencing of the 16S rRNA gene. For the 16S rDNA analyses, the template

200 DNA was combined with 2X PCR Mastermix (Promega, Madison, WI) and PCR primers 91E (5'-  
201 GGAATTCAAAGAATTGACGGGGGC-3') and 13B (5'-CGGGATCCCAGGCCCGGAACGTATTAC-3')  
202 to amplify a 440-bp fragment of the 16S rDNA using a PCR protocol with an initial denaturation  
203 at 95°C, followed by 40 cycles of 1 min at 94°C, 1 min at 55°C and 2 min at 72°C with a final 5  
204 min extension at 72°C (16). The PCR products were separated by agarose gel electrophoresis (2%  
205 E-gel, Life Technologies, Grand Island, NY) to verify the presence of a product, purified by  
206 membrane filtration and prepared for DNA sequencing with BigDye Terminators (Applied  
207 Biosystems, Foster City, CA). The amplified products were sent to the core sequencing facility  
208 at the University of Arkansas for Medical Sciences (UAMS) for sequencing using the BigDye  
209 chemistry on an ABI 3130XL sequencer (Applied Biosystems). The resultant sequences were  
210 visually inspected and submitted to GenBank to identify the bacterial genus and, in most cases,  
211 species (17).

212

### 213 **Identification and Specific Bacterial Numbers Present in the STPs**

214 **Sample Preparation.** An approximately 0.4 g sample of each tobacco product was collected and  
215 the bacterial DNA was extracted using the UltraClean Soil DNA Isolation Kit (MoBio Laboratories,  
216 Carlsbad, CA) according to the manufacturer's instructions. The DNA was quantified using an  
217 ND-1000 spectrophotometer (NanoDrop Technologies, Wilmington, DE) and used as a template  
218 for PCR reactions to amplify the V1/V2 and V6 variable regions of the 16S rRNA genes. To  
219 amplify the V1/V2 16S rRNA region, PCR reactions were prepared with the purified DNA, PCR  
220 master mix and associated primers presented in Table 2.

221 To amplify the V1/V2, one set of primers was used that contain 454-specific adaptors  
222 (Roche/454 LifeSciences; Bradford, CT), linker nucleotides (underlined in Table 2), a unique STP-  
223 specific 6-base barcode (Xs, in the reverse primer), and the specific V1/V2 bacterial primers  
224 (bolded). The PCR reactions were carried out as previously described (18). The PCR reactions  
225 were quantified using a PicoGreen assay (Invitrogen, Carlsbad, CA) and the reaction products  
226 pooled in equimolar amounts of PCR products for 454 LifeSciences Titanium sequencing at the  
227 David H. Murdock Research Institute (Kannapolis, NC).

228 To amplify the V6 regions, PCR reactions were carried out using the multiplex sets of  
229 primers described by Huber et al. (2007). The sets include 5 forward and 4 reverse primers  
230 containing 454-specific adaptors, linker nucleotides (underlined in Table 2), a unique 6 base  
231 barcode (Xs, in the forward primers), and the specific V6 bacterial primers (bolded). The PCR  
232 reactions were carried out as previously described (19). The PCR reactions were quantified,  
233 pooled and sequenced as described above for the V1/V2 region.

234 Following the sequencing runs, the DNA sequence data were checked for quality and  
235 the pooled sequence runs were then sorted based on their unique barcode and primer  
236 sequences using the Newbler program (Roche/454 LifeSciences). The sorted sequence  
237 flowgram files were submitted to the MG-RAST sequence analysis pipeline (Argonne National  
238 Laboratory, Argonne, IL) and converted to FASTQ format. The taxonomic identifications were  
239 done using MG-RAST's Best Hit Classification algorithm to compare sequences to the  
240 GreenGenes databases to determine the number of sequences corresponding to specific  
241 operational taxonomic units (OTU) for each of the STPs (20, 21). The resultant OTU data  
242 (numbers of sequence reads per OTU) were exported to Microsoft Excel to determine the  
243 relative percentages of the different taxa present in each sample. Sample populations were  
244 evaluated in MG-RAST, rarefaction curves were generated and subsequent alpha diversity  
245 (Shannon diversity) calculated to evaluate the population composition of each sample (20, 21).  
246 Principal Coordinate Analysis (PCoA) was carried out in MG-RAST and phylogenetic analysis  
247 using the Euclidean distance (BioNumerics; Applied Maths, Austin, TX) were used to evaluate  
248 population differences between the samples at the Class level.

249 **Denaturing Gradient Gel Electrophoresis (DGGE).** DGGE was used to evaluate potential  
250 changes in the bacterial population in the STPs over the sampling period. Total bacterial DNA  
251 was isolated from each tobacco sample, using the UltraClean Soil DNA Isolation Kit, and the  
252 DNA concentration was quantified using an ND-1000 spectrophotometer as described above.  
253 Isolated DNA was stored at -80°C to facilitate normalization of DNA concentrations across all  
254 samples (days 1, 3, 5, 8 and 15) for a particular STP. For each of the DNA samples for a product,  
255 the DNA concentrations were normalized and subjected to PCR using a common master mix.  
256 PCR primers (GC-clamp-340F [5'-TCCTACGGGAGGCAGCAG - 3'] and 518R [5'-

ATTACCGCGGCTGCTGG- 3']) were used to amplify the V3 region of the 16S rRNA gene as previously described (22, 23). The DNA concentrations of the PCR reaction products were normalized and 500 ng of each sample from a particular tobacco product were separated on a single gel using denaturing conditions of Muyzer et al. (1993) as modified by Martin et al. (2007). This approach, including each of the time point samples from each tobacco product on a single gel, allowed detection of potential changes in the microbial populations over the sampling period (24, 25). The DGGE gels were stained using GelStar™ Nucleic Acid Gel Stain (Lonza, Basel, Switzerland) and digitally photographed. Banding patterns were compared to identify changes in band position and intensity, which indicate population changes.

## RESULTS:

### Tobacco Characterization

A total of 90 individual tobacco samples representing 15 different smokeless tobacco products were tested. These sample groups have been named AR1, DC1, AR2, DC2, AR3 and DC3 (AR for Arkansas or DC for Washington, DC, and the number for the sampling period: November 2012 (1), March 2013 (2) and July 2013 (3); Table 1).

**Moisture.** The moisture levels were relatively consistent across the study for the same products, with the exception of the DC1 samples, which were significantly higher than the other sample sets and those previously reported in the literature (26, 27). Based on troubleshooting and additional testing, a problem with one of the reagents was identified and the reagent replaced for subsequent testing, therefore the DC1 samples were not included in the average results (Table 3). Overall, the moist snuff products, including both loose and pouch types had the highest moisture content, followed by the snus and the chewing tobacco. The moist snuff products on average had moisture contents between 522 and 583 mg water/g of tobacco. The snus products averaged between 269 and 315 mg water/g of product and the chewing tobacco between 252 and 271 mg water/g of product.

**pH.** There were also some differences among the product types in the pH of the products (Table 2), with moist snuff having higher pH levels (pH 7.4-8.2) and the chewing tobacco samples among the lowest (pH 5.5-6.0). The snus samples were more variable, with the

286 Brand E Snus Mellow having an average pH of 7.6, while the Brand F Snus Mint (pH 5.9) and  
287 Brand B Snus Mint (pH 6.4) had considerably lower average pH values.

288 **Particle Sizes.** To determine the product sizes of the individual fragments, 100 individual  
289 particles were measured and placed into size categories (ranging from  $\leq 1 \times \leq 1$  mm to  $> 2 \times > 8$   
290 mm) based on the length and width due to challenges in measuring some of the smallest  
291 fragments accurately. The mode (most commonly detected) particle sizes were determined for  
292 each product (Table 3). Figure 1 shows a representative of each type of product sampled. The  
293 chewing tobacco had by far the largest particles ( $> 2 \times > 8$  mm), followed by the loose moist snuff  
294 (modes ranging from  $\leq 1 \times 2$  mm to  $1 \times > 8$  mm), and the pouched moist snuff and snus had the  
295 smallest particle sizes (modes from  $\leq 1 \times \leq 1$  mm to  $\leq 1 \times 2$  mm) (Table 3). The pouches provide a  
296 means to keep the very fine particle sizes contained for the user.

297 **Microbial Loads.** The results of the initial sampling period indicated that there were  
298 differences in the diversity and number of microorganisms in the different smokeless tobacco  
299 samples. Therefore, total aerobic plate counts were carried out for each sample during the  
300 second and third sampling periods to determine the number of CFU of bacteria per gram of  
301 product. The moist snuff products had the highest microbial loads (Table 4), followed by some  
302 of the chewing tobacco samples (the Brand G products had significantly higher loads than the  
303 Brand H samples;  $p < 0.05$ ), and the lowest loads were in the snus samples. Two of the products  
304 (Brand E Snus Mellow and Brand F Snus Mint) did not have any growth during the aerobic plate  
305 count studies and the third product (Brand B Snus Mint) had only a single colony on one  
306 sampling. Table 4 shows the mean number of CFUs/g of product across the four sample sets  
307 tested. In general, the moist snuff samples averaged around  $10^6$  CFU/g, which was  
308 considerably higher than the other products, with the exception of the Brand G Chewing  
309 Tobacco, which averaged approximately  $7 \times 10^5$  CFU/g. All of the moist snuff samples and all  
310 but Brand H chewing tobacco had significantly higher microbial loads ( $p < 0.05$ ) than Brand B  
311 Snus Mint, which was the only snus sample with microbial growth.

312 **Sample Recovery Experiments.** Initial experiments were conducted to determine  
313 whether there were likely inhibitory substances or product conditions that limited the ability of  
314 microorganisms to grow in some of the samples. Three sample types that had different

315 bacterial loads in the earlier portions of the study, including moist snuff (Brand C Wintergreen)  
316 with high levels, chewing tobacco (Brand H Chewing Tobacco) with intermediate levels, and  
317 snus (Brand F Snus Mint) with low levels were evaluated. The samples were autoclaved, with  
318 the exception of a subset of snus samples that had a low background of microorganisms, and  
319 were included to see if autoclaving affected growth. Overall, when the products were seeded  
320 with *S. aureus*, there was significantly higher recovery of organisms from the moist snuff  
321 samples (62%) than the other samples (<5%;  $p<0.05$ ). The lowest recovery was from the  
322 chewing tobacco samples, where the average recovery was approximately 1.1%; however, the  
323 difference was not significantly lower than the recovery from snus samples. There appeared to  
324 be a slightly higher recovery from the non-autoclaved sample of snus than the autoclaved  
325 sample (4.9% vs. 1.4%); however, this may be due to the background microflora of the product  
326 (there were low levels of growth in some of the non-autoclaved samples). The recoveries of *P.*  
327 *aeruginosa* were much lower in general, with the highest average percent recovery from moist  
328 snuff (3.8%), and the average recovery from each of the samples less than 1.0%. Likewise, the  
329 recoveries of *B. subtilis* were low, with the highest average recovery of 1.2% for the moist snuff  
330 sample and the lowest at 0.4% for the chewing tobacco. The observed differences in recoveries  
331 of *P. aeruginosa* and *B. subtilis* from the various products did not reach the level of significance.

### 333 **Detection of Culturable Bacteria**

334 The containers of STPs were sampled over a 15-day period during each set of  
335 experiments. Over 2,500 different bacterial colonies that appeared to have unique  
336 morphologies on the individual sample plates (individual STP extract spread on each plate)  
337 were selected. At most sampling periods, the moist snuff samples had higher numbers and  
338 apparent diversity of bacterial colonies than the snus and some chewing tobacco samples.  
339 Table 5 shows which samples were positive for bacterial growth and the numbers of colonies  
340 selected on the different culture media, sampling days and periods. There was no growth  
341 observed on any of the MacConkey agar plates, indicating the likely absence of Gram-negative  
342 enteric bacteria. On a majority of sampling days, no bacteria were grown from most snus  
343 samples. This intermittent positivity is likely due to a low level of bacterial content or unequal

344 distribution of organisms, such that there were not always bacteria in the suspensions that  
345 were plated. Additionally, there did not appear to be an increase in the number of positive  
346 samples in the snus products over the sampling period, indicating that there was likely no active  
347 growth of the bacteria in the products. The chewing tobacco samples were more variable, with  
348 Brand G products having a higher percentage of positive samples than Brand H. These findings  
349 mirror the microbial load studies described above.

350 To identify the bacterial organisms cultured, 16S rRNA gene sequencing indicated that  
351 over 90% of bacteria isolated belonged to the genus *Bacillus*. The most common species  
352 identified (in order of frequency) were *B. pumilus*, *B. licheniformis*, *B. safensis* and *B. subtilis*. Of  
353 the non-*Bacillus* species, *Oceanobacillus*, *Staphylococcus* (including *S. epidermidis* and *S.*  
354 *hominis*) and *Tetragenococcus* were the most common genera (Supplemental Table S1). The  
355 *Oceanobacillus* strains were most commonly isolated from the chewing tobacco samples,  
356 whereas most of the staphylococci were isolated from the snus samples.

357

#### 358 **Detection of Total Bacterial Populations**

359 16S rRNA gene sequencing was done to determine the populations of bacteria, including  
360 uncultured bacteria, associated with the STPs. Sequences of approximately 330 bases were  
361 obtained from the V1/V2 region, which in most cases allowed classification of taxa down to the  
362 genus level; however, for comparison among the samples, the populations were evaluated at  
363 the class level (Figure 2 and Supplemental Figure S1). Across all three sampling periods the  
364 average number of sequencing reads per sample per run was 20,966; however, sample DC1-5  
365 (Brand C Wintergreen) did not provide adequate sequence data to analyze efficiently (26 reads).  
366 The predominant class in most of the samples was the Bacilli, while some of the others had a  
367 higher proportion of Gammaproteobacteria. The alpha (Shannon) diversity of the samples  
368 ranged from 1.80 (removing sample DC1-5, with very low sequence coverage) to 19.07  
369 (Supplemental Table S2). There was little similarity of alpha diversity value calculated across  
370 the same product types. Likewise, when the results from the samples were compared to one  
371 another using PCoA and phylogenetic analyses, the samples from the same types of products  
372 generally did not cluster together; however, several of the samples from the third sample

373 period appeared to form separate groupings (Supplemental Figures S2 and S3). When those  
374 samples with a high proportion of Bacilli were further examined, the predominant bacterial  
375 DNA sequences identified were from the genera *Tetragenococcus*, *Carnobacterium*,  
376 *Lactobacillus*, *Geobacillus*, *Bacillus*, and *Staphylococcus*. Some of these genera were also  
377 cultured from the STP samples; however, others were not detected by culturing under aerobic  
378 conditions. Thus, during the third sampling period, a set of tobacco suspensions plated on  
379 brain-heart infusion (BHI) agar were incubated anaerobically to determine whether there were  
380 differences in bacterial species isolated. The organisms that grew were sequenced and  
381 determined to be members of the genus *Bacillus* and matched the aerobic culture results (data  
382 not shown). The data for the V1/V2 sequencing are publically available through the MG-RAST  
383 program (<http://metagenomics.anl.gov>) deposited as project 10176 and the accession numbers  
384 4573000.3-4573089.3 and 4574738.8 (Supplemental Table S2).

385       The analyzed V6 region fragment is smaller in size, typically around 80 bases in size.  
386 There was an average of 19,552 sequence reads per sample sequenced; however, two samples  
387 (DC2-8 [Brand A Pouches] and DC3-1 [Brand A Straight]) did not provide adequate sequence  
388 data to analyze efficiently (20 and 45 reads, respectively). As with the V1/V2 sampling, the  
389 predominant classes identified were the Bacilli and Gammaproteobacteria; however, a  
390 relatively high proportion of the sequences could not be fully discriminated at the class level  
391 and were listed as unclassified bacteria or unclassified Firmicutes (the phylum including the  
392 class Bacilli) (Figure 3 and Supplemental Figure S4). The most commonly identified genera from  
393 the V6 analyses and comparison to the Greengenes database were *Bacillus*, *Aeribacillus*,  
394 *Geobacillus*, *Tetragenococcus*, *Corynebacterium*, *Halomonas*, *Staphylococcus*, and  
395 *Anoxybacillus*. The alpha (Shannon) diversity of the samples ranged from 1.37 to 21.27  
396 (Supplemental Table S2). When compared to the results from the V1/V2 analyses, there was  
397 little consistency in the alpha diversity detected; such that samples with comparatively low  
398 diversity with the V1/V2 had higher levels detected from the V6 region, and vice versa. As with  
399 the V1/V2 results, PCoA and phylogenetic analysis showed little clustering based on product  
400 type or sampling period (Supplemental Figures S5 and S6). The data for the V6 sequencing are

publicly available through the MG-RAST program (<http://metagenomics.anl.gov>) deposited as project 10910 and the accession numbers 4582827.3-4582916.3 (See Supplemental Table S2).

#### **Evaluation of Bacterial Population Changes in Open Product**

The comparison of DGGE profiles of total bacteria isolated indicated that the bacterial populations in some of the open product samples varied during the sampling periods (Supplemental Figure S7). Overall, at least 21 of the 90 (23.3%) individual samples analyzed displayed changes in the banding profiles of the samples, indicative of population changes. In all but five instances, the products with the apparent bacterial population changes had variability in more than a single sampling batch. The only samples that did not display any population changes in any of the samples during the sampling periods were the three snus products (Supplemental Table S3).

#### **DISCUSSION:**

This project was undertaken to gain a better understanding of the microbial populations that may be present in STPs. Microbial populations in STPs are an important consideration for the protection of public health and for FDA as it develops new regulations under section 906 of the Federal Food, Drug, and Cosmetic Act. A potential risk for STP users is that the products could carry pathogenic or opportunistic microorganisms that may result in the development of an infectious disease. This is a concern, in part, because STPs are typically held for extended periods of time in close contact with the oral mucosa. Another potential risk associated with microbial contamination is the development of microbial metabolic byproducts that may be harmful to consumers, such as microbial toxins and carcinogens. Thus, the goals of the present study were to determine the types and numbers of microorganisms present in the STPs to create a microbiological baseline for STPs and to lay the foundation for further studies to evaluate the potential microbial risks of smokeless tobacco use.

The major objectives of the study were to identify the bacterial microorganisms that are present in a convenience sample of STPs available to consumers in two geographically distinct locations and to determine the impact of temporal changes on the microbial communities

430 present in STPs. Fifteen different products representing four major types of STPs were analyzed  
431 over the study period. A potential limitation of the study is that for each type of product, a  
432 small cross section of the available products were tested; however, efforts were made to  
433 include a variety of products and manufacturers to minimize this potential concern. For  
434 example, the moist snuff samples, which have the highest market share of users, had the  
435 highest number of products sampled. The most common bacteria identified among the STPs in  
436 the culture-based experiments were members of the genus *Bacillus* (Supplemental Table S1).  
437 These organisms are able to form endospores, which resist drying, high temperature, and other  
438 factors that inhibit the growth and reproduction of vegetative microorganisms. The species of  
439 *Bacillus* that we detected are also fairly common in the environment and are not often  
440 associated with acute illness in humans; however, *B. licheniformis* and *B. pumilus* are potential  
441 causes of pulmonary inflammation and opportunistic infections (11). In addition, *B. pumilus*  
442 and *B. subtilis* have been identified as causative agents in spice-associated outbreaks and may  
443 produce a mild toxin after growing to a large population that may result in illness (12, 13).  
444 Another potential concern regarding the bacilli is that some of the *Bacillus* species, including *B.*  
445 *pumilus*, *B. licheniformis* and *B. subtilis*, are able to reduce nitrates to nitrites (28). Nitrites are  
446 important precursors for the nitrosation of nicotine to form the carcinogenic tobacco-specific  
447 N'-nitrosamines (TSNAs) (29, 30). The presence of these microorganisms in the STPs suggests  
448 the possibility for TSNA formation after packaging. This phenomenon would be consistent with  
449 earlier studies that found that the levels of TSNAs in certain STPs stored at ambient conditions  
450 increased over time (31, 32).

451 Strains of *S. epidermidis* and *S. hominis* also are able to reduce nitrate and present  
452 potential health concerns as opportunistic pathogens, especially for immunocompromised  
453 users. Both staphylococci have been reported to cause bacterial endocarditis (heart valve  
454 infection), which arises due to transmission to the heart via the bloodstream (33). STP users  
455 often have problems with gingivitis and other oral health issues, which may allow bacterial  
456 entry into the bloodstream (34). However, to our knowledge no studies have yet shown a  
457 causal link between STP use and bacterial endocarditis.

458 *Tetragenococcus* and *Oceanobacillus* are members of the families Enterococcaceae and  
459 Bacillaceae, respectively, and some species are associated with fermented foods. Thus, it is  
460 possible that these organisms may be present in the production of the different tobacco  
461 products. *Oceanobacillus* was most often detected in the chewing tobacco samples.  
462 Interestingly, some of the better characterized *Oceanobacillus* isolates in the literature are  
463 identified as being more alkaliphilic (35) and yet the chewing tobacco samples had the lowest  
464 pH levels.

465 A potential concern with the experimental results was the lack of positive cultures from  
466 the snus samples. The other STP types had relatively high microbial loads, thus experiments  
467 were conducted to determine whether there were inhibitory substances or product conditions  
468 that limited the ability of microorganisms to grow in the snus samples. In the seeding and  
469 recovery experiment, both the snus and chewing tobacco appeared to be inhibitory towards  
470 bacterial growth. These findings suggest that this may be the results of the lower pH or  
471 moisture content in the snus and chewing tobacco samples or the presence of antimicrobial  
472 compounds in these products. For example, nicotine has been shown to impact the growth of  
473 certain bacteria associated with dental caries (36, 37) .

474 When the pyrosequencing results from the V1/V2 region of the 16S rRNA genes in the  
475 total DNA isolated from many STPs were compared to the culturing results, there were  
476 instances of incongruence. While members of the genera *Tetragenococcus*, *Geobacillus*,  
477 *Bacillus* and *Staphylococcus* were among the top identified taxa by both sequencing of the  
478 V1/V2 region and culturing (Figure 2 and Supplemental Figure S1), other genera including  
479 *Carnobacterium*, *Lactobacillus* and *Corynebacterium* were common among the sequences but  
480 not detected by culture. There are multiple possibilities for these differences between the  
481 pyrosequencing and culture results, including non-optimal culturing conditions or amplification  
482 of DNA from non-viable organisms. For example, many lactobacilli are facultative anaerobes or  
483 microaerophiles, and may not grow efficiently under the aerobic culture conditions used for  
484 isolation and culture. When culture plates from STP samples were incubated under anaerobic  
485 conditions, the bacteria that grew were the same *Bacillus* species that were detected with the  
486 standard aerobic culturing methods. The probable explanation for the discrepant results is that

the STPs had fairly high loads of lactobacilli, which may have grown during the fermentation process in the production of the finished STP, but were killed during further processing. In this case, their DNA could remain in the product and be amplified in the initial steps of the sequencing experiments. In future experiments, it may be preferential to initially isolate bacterial RNA, which is much less stable than DNA and therefore may provide a more positive correlation with viability status, and use it as the starting material for sequencing (38). This approach would minimize the carryover detection of dead organisms and maintain the population ratios of organisms in the sample. An alternative approach would be to include a short enrichment step with the samples before bacterial isolation and DNA extraction. This approach would minimize the impact of the dead organisms and potentially activate *Bacillus* spores making DNA extraction more efficient, but unfortunately would likely distort the ratios of bacterial populations.

The V6 pyrosequencing results in general were similar to those of the V1/V2 analyses, however a greater proportion of sequences were “unclassified” at each of the taxonomic levels using both Ribosomal Database Project (RDP) and GreenGenes comparisons. These ambiguous results were likely due to the short sequence length that was amplified, sequenced and searched. The V6 region was only about 80 base pairs in size. This target worked well for intestinal bacteria (19), where the datasets are likely much richer; however, some of the microorganisms in STPs may not be well represented in the sequence database, thus preventing specific matches and leading to the higher degree of “unclassified” samples. When representative sequence reads from the unclassified bacteria category were submitted for BLAST searching, the highest scoring matches returned were generally to the lactobacilli, which is consistent with the V1/V2 findings. As with the V1/V2 results, among the most commonly identified genera were *Bacillus*, *Geobacillus*, *Tetragenococcus*, *Corynebacterium*, *Halomonas*, and *Staphylococcus* (Figure 3 and Supplemental Figure S4).

Interestingly the V6 sequencing results provided added resolution for the *Proteobacteria*, especially the Alpha-, Beta- and Deltaproteobacteria in the samples. This result was likely the result of the PCR primer sets used to amplify the products. The V6 region approach used five forward and four reverse primers that included several degenerate bases

516 that likely allowed for a more efficient amplification of a wider array of DNA templates present  
517 in the tobacco samples. The V1/V2 approach used a single pair of primers, which likely  
518 impacted the efficiency of amplification of some taxa. These observations are consistent with  
519 the generally higher alpha diversity calculations for the V6 sequences than for the V1/V2  
520 samples (average Shannon Diversity of 9.85 vs. 7.00, respectively).

521 The ability to amplify enough DNA templates for sequencing was difficult in several  
522 samples, even though there was ample DNA template based on the DNA concentrations and  
523 the results of the DGGE experiments. Because the DGGE primers were outside the region of  
524 the V1/V2 primers, for the third sampling, the DNA template was initially amplified with the 27F  
525 forward primer and the 518R DGGE primer followed by amplification with the V1/V2 primers  
526 (27F and 338R) and the resultant sequence results were more robust. These results included an  
527 increased amplification of the Proteobacteria that were poorly amplified using the V1/V2  
528 primers, but detected in the V6 sequences. Related to these findings, the alpha diversity  
529 results were higher for several of the samples from the third sampling period. Sixteen of the 30  
530 samples with the highest Shannon Diversity among the V1/V2 samples were from the third  
531 sampling period (Supplemental Table S2). Additionally, the result of this amplification change  
532 can likely be observed in both the PCoA and phylogenetic analyses, whereby several samples of  
533 the third sampling (AR3 and DC3 samples) were separated from many of the samples of  
534 sampling 1 and 2 (Supplemental Figures S2 and S3). This divergence is likely attributable to the  
535 amplification of increased proportions of the Proteobacteria, Actinobacteria and Clostridia,  
536 which can be observed in the bottom cluster of Supplemental Figure S3.

537 Several genera identified by sequence analyses from the various STPs have been  
538 identified as part of the oral microbiome. Among suspected periodontal pathogens, some STPs  
539 were positive for sequences representing the genera *Eubacterium*, *Prevotella* and  
540 *Porphyromonas* (39), although in relatively low numbers and in a limited number of samples.  
541 Other genera identified by pyrosequencing, including *Lactobacillus* and *Actinomyces*, have been  
542 suggested to play roles in dental caries pathogenesis (40). The lactobacilli sequences were  
543 among the most commonly identified among the V1/V2 sequences, but were at a much lower  
544 proportion among the V6 sequences. This finding may be due to the increased ability of the

545 V1/V2 sequencing to map to specific sequences in the datasets, which is likely due to their  
546 larger fragment size. Overall, many of the taxa detected in the STP samples have been  
547 reported as part of the normal microbiota of the oral cavity, including many of the members of  
548 *Firmicutes*, *Proteobacteria* and *Actinobacteria* (41). The STP samples had much lower  
549 proportions of *Bacteroides* and *Fusobacterium* than have been reported as part of the normal  
550 oral microbiota (40, 42).

551 There did not appear to be significant changes in the bacterial populations over the  
552 sampling periods. Similar numbers of distinct colonies (Table 5 and Supplemental Table S1)  
553 were detected across the sampling period and the morphologies detected were consistent.  
554 When the isolates were sequenced, similar species were identified across the sampling days.  
555 With DGGE, about 21 of 90 samples appeared to have different patterns across the sampling  
556 periods; often bands present on earlier days (e.g., 1 and 3) gradually diminished over the  
557 sampling period. These results could reflect the degradation of DNA from dead microorganisms  
558 present in the samples, such as those detected with the pyrosequencing studies. More work  
559 will need to be done to verify this hypothesis. Based on the culture findings and the DGGE  
560 results, the bacterial populations appeared to be fairly consistent during the sampling periods.

561 In summary, the moisture and pH levels that we detected in the STP samples are  
562 consistent with data reported elsewhere for similar products (26, 27). The moist snuff samples  
563 had the highest levels of bacterial contamination (both in diversity and number of organisms),  
564 which may coincide with their more neutral pH and higher moisture levels. The snus samples  
565 and some of the chewing tobacco samples harbored significantly fewer bacteria than the moist  
566 snuff samples, potentially indicating that the relatively high levels of bacteria in moist snuff may  
567 warrant greater attention in future studies. The study findings provide baseline data on the  
568 microbial content of STPs, which is important to assess the potential risks to the users, aid in  
569 the assessment of manufacturing processes and assist FDA in establishing regulations. The fact  
570 that many of the bacterial species identified have the ability to reduce nitrate to nitrite and  
571 thus potentially contribute to the production of highly carcinogenic TSNA also warrants further  
572 attention in future studies.

573

709

710 **Figure 1.** Types of smokeless tobacco products evaluated in the study: A) loose moist  
711 snuff, B) moist snuff in pouches, C) snus, and D) chewing tobacco.

712

713 **Figure 2:** Cumulative pyrosequencing results for the V1/V2 region of the 16S rRNA  
714 analysis of each of the different types of smokeless tobacco samples analyzed. The bar  
715 graph indicates the percent of sequences detected that belonged to a particular  
716 bacterial class. The classes of organisms and color schemes are presented on the right  
717 side of the figure. The DNA sequences identified as chloroplasts have been removed  
718 due to their likely plant origin, rather than microbial populations.

719

720 **Figure 3:** Cumulative pyrosequencing results for the V6 region of the 16S rRNA analysis  
721 of each of the different types of smokeless tobacco samples analyzed. The bar graph  
722 indicates the percent of sequences detected that belonged to a particular bacterial class.  
723 The classes of organisms and color schemes are presented on the right side of the figure.  
724 The DNA sequences identified as chloroplasts have been removed due to their likely  
725 plant origin, rather than microbial populations.

## REVIEW ARTICLE

# Comprehensive review of epidemiological and animal studies on the potential carcinogenic effects of nicotine *per se*

Hans-Juergen Haussmann<sup>a</sup> and Marc W. Fariss<sup>b</sup><sup>a</sup>Toxicology Consultant, Roesrath, Germany; <sup>b</sup>Altria Client Services LLC, Richmond, VA, USA**ABSTRACT**

The effects of long-term use of nicotine *per se* on cancer risk, in the absence of tobacco extract or smoke, are not clearly understood. This review evaluates the strength of published scientific evidence, in both epidemiological and animal studies, for the potential carcinogenic effects of nicotine *per se*; that is to act as a complete carcinogen or as a modulator of carcinogenesis. For human studies, there appears to be inadequate evidence for an association between nicotine exposure and the presence of or lack of a carcinogenic effect due to the limited information available. In animal studies, limited evidence suggests an association between long-term nicotine exposure and a lack of a complete carcinogenic effect. Conclusive studies using current bioassay guidelines, however, are missing. In studies using chemical/physical carcinogens or transgenic models, there appears to be inadequate evidence for an association between nicotine exposure and the presence of or lack of a modulating (stimulating) effect on carcinogenesis. This is primarily due to the large number of conflicting studies. In contrast, a majority of studies provides sufficient evidence for an association between nicotine exposure and enhanced carcinogenesis of cancer cells inoculated in mice. This modulating effect was especially prominent in immunocompromised mice. Overall, taking the human and animal studies into consideration, there appears to be inadequate evidence to conclude that nicotine *per se* does or does not cause or modulate carcinogenesis in humans. This conclusion is in agreement with the recent US Surgeon General's 2014 report on the health consequences of nicotine exposure.

## Introduction

Nicotine delivery systems (Shahab et al. 2013; Benowitz 2014) continue to evolve for nicotine replacement therapy (NRT) products and for electronic nicotine delivery systems (ENDS, e-cigarettes). As a result, millions of people are exposed to nicotine *per se* on a daily basis resulting in blood nicotine levels of approximately 5–40 ng/ml (Table 1). These products are often touted as “clean” nicotine delivery products as they contain pharmaceutical-grade nicotine as the only added active ingredient and do not contain tobacco (Schneider et al. 2001; Benowitz 2014; Flora et al. 2016). The recommended duration of use for approved NRT products is 8–12 weeks depending on the product type (US Food and Drug Administration 2013). The FDA, however, recently proposed the possibility of a 6-month extension of NRT use with healthcare provider consultation (US Food and Drug Administration 2013; Fucito et al. 2014). It seems that uncertainty regarding the potential adverse health effects (including cancer risk) of long-term use of

nicotine *per se* may be, in part, responsible for the modest increase in the proposed duration of NRT use (Shields 2011; Grando 2014).

At present, nicotine is not considered a human carcinogen as noted in numerous statements from authoritative bodies (Table 2). For example, the latest report of the US Surgeon General concluded that “the evidence is inadequate to infer the presence or absence of a causal relationship between exposure to nicotine and risk for cancer” (US Department of Health and Human Services 2014, p. 8). In addition, the Tobacco Advisory Group of the UK Royal College of Physicians stated that there is no direct evidence that NRT is carcinogenic (UK Royal College of Physicians 2007). NRT product warning label statements (health-related) provide authoritative bodies with the opportunity to communicate their concern about the potential harmful effects of these products. For NRT products, the labels do not warn about potential cancer risks (US Food and Drug Administration 2015). Numerous review/opinion publications also suggest that the scientific evidence (animal and human) does not support a carcinogenic effect for long-term nicotine exposure (Benowitz 2011; Cardinale et al. 2012; Hecht 2012a, 2012b International Agency for Research on Cancer 2012, p. 134; Warren & Singh 2013; Schaal & Chellappan 2014; Sanner &

Grimsrud 2015). A comprehensive evaluation of the published scientific literature on this topic (animal and human studies), however, is missing.

Carcinogenesis is a multi-staged process which operationally involves three stages: initiation, promotion and progression (Klaunig 2013). A complete carcinogen is a chemical that induces tumors, by itself, usually with initiating, promoting, and progressing properties. Genotoxicity is a required property of initiators. The available data on a genotoxic potential of nicotine are conflicting and have not been critically reviewed. Genotoxicity was not observed for nicotine or its four major metabolites at concentrations of up to 1 mg/ml in the *Salmonella* reverse mutation assay and in a sister chromatid exchange assay in Chinese hamster ovary cells (Doolittle et al. 1995). However, in recent *in vitro* genotoxicity studies examining strand-breaking activity assessed by the Comet assay, chromosome aberration or micronucleus formation, nicotine was found to be active in a concentration range between 160 ng/ml and 650 µg/ml (Argentin & Cicchetti 2004; Ginzkey et al. 2012; 2013; Bavarva et al. 2014; Ginzkey et al. 2014a, 2014b). This range is beyond the systemic nicotine levels achieved by using NRT products (Table 1), but at local sites of entry, such as at respiratory tract or oral epithelia, nicotine concentrations may indeed be higher than systemic concentrations (Jarvis et al. 1984). Genotoxic effects at systemically relevant nicotine concentrations (16 ng/ml) were reported in a few studies, such as in a cytokinesis-blocked micronucleus assay (Kleinsasser et al. 2005) and in a chromosomal aberration assay (Demirhan et al. 2011). Overall, definitive studies to determine the genotoxic potential of nicotine in users of nicotine delivery systems are missing.

Concern has been raised by authoritative bodies that nicotine might act as a promoter and/or progressor of an initiated carcinogenic process (Table 2). From a mechanistic standpoint, there is considerable evidence that nicotine exposure can affect many of the cellular processes that are considered important for the promotion or progression of the carcinogenic process. Numerous reviews have been published summarizing these mechanistic findings (Improgo et al. 2011; Cardinale et al. 2012; Jensen et al. 2012; Lee & Cooke 2012; Russo et al. 2012; Schuller 2012; Chu et al. 2013; Warren & Singh 2013; Grando 2014; Niu & Lu 2014; Schaal & Chellappan 2014; Schuller 2014). For example, nicotine has been reported to stimulate cell proliferation, inhibit apoptosis, induce cell migration and invasion, induce angiogenesis and inhibit immune functions. Such effects were often observed *in vitro* at systemically and/or locally relevant nicotine concentrations. In particular, the role of nAChRs in triggering intracellular signaling pathways that influence the carcinogenic process have been emphasized (Grando 2014).

Nicotine *per se* is a unique active ingredient for a consumer product in that the majority of nicotine’s effects are mediated by binding and activating nicotinic acetylcholine receptors (nAChRs) in a wide variety of neuronal (central and peripheral nervous system) and non-neuronal tissue. Consequently, nicotine exposure affects numerous systems, including neurologic, neuromuscular, cardiovascular, respiratory, immunological and gastrointestinal. The presence of different types of nAChRs, receptor upregulation and receptor desensitization influences these complex physiological effects. Numerous studies in experimental animals demonstrate that nicotine exposure results in a dramatic increase in both nAChR numbers and receptor desensitization in the

brain resulting in tolerance to the central effects of nicotine (Marks et al. 1985; Renda & Nashmi 2014). In contrast, little is known about the response of peripheral nAChRs in regard to receptor upregulation and desensitization following nicotine exposure (Lam et al. 2016). Similarly, many types of cancer cells express a wide variety of nAChRs (Improgo et al. 2013), but few studies have characterized the effect of nicotine on receptor numbers and desensitization (Brown et al. 2013).

Based on the mechanistic studies, a case for biological plausibility has been proposed for a potential role of nicotine in carcinogenesis. Therefore, it seems appropriate for the present review to critically evaluate the strength of published scientific evidence, in both human and animal studies, for potential carcinogenic effects of nicotine *per se*. The potential of nicotine *per se* to act as a complete carcinogen or as a modulator of an initiated carcinogenic process are assessed in this review. Toxicokinetic considerations relevant for this evaluation are also briefly summarized. Mechanistic data on the potential carcinogenic effects of nicotine *per se*, however, will not be evaluated, as numerous mechanistic studies have recently been reviewed (see above). Finally, the words nicotine *per se* and nicotine are used synonymously in this review.

Methods

For the present review, evaluations of relevant published literature were carried out according to processes described in the sections below, which were adapted

or modified from a wide variety of published frameworks (Hill 1965; International Agency for Research on Cancer 2007; Organisation for Economic Co-operation and Development 2009; Rhomberg et al. 2011; Goodman et al. 2013; Rhomberg et al. 2013; Prueitt et al. 2014; Willhite et al. 2014). These frameworks, including our own, have similar processes such as defining the study question, gathering relevant studies using inclusion and exclusion criteria, evaluating studies for quality, consistency and relevance, integrating evidence on related topics to draw conclusions and using these conclusions to determine a strength of evidence classification (Rhomberg et al. 2013).

Study question

The present review was conducted to answer the question: What is the potential carcinogenic effect of nicotine *per se*, at levels found in users of nicotine delivery systems? In this review, nicotine delivery systems refer to products that contain nicotine as the only added active ingredient, that contain pharmaceutical grade nicotine and do not contain tobacco. Due to the large number of *in vitro* and *in vivo* studies on this topic (Figure 1), we chose to limit our answer to this question using published human and animal studies. *In vitro* studies and mechanistic data will not be critically evaluated in the present review. Thus, the objective of this review is to critically evaluate the strength of published scientific evidence, in both human and animal studies, for the potential carcinogenic effects of nicotine

Figure 1. Overview of findings from literature searches and criteria used for the inclusion and exclusion of publications for critical evaluation. \*The total number is only 74 because several publications include both complete and modulating cancer studies.

*per se*. In animal studies, the potential of nicotine to act as a complete carcinogen or as a modulator (stimulator) of carcinogenesis is evaluated. The goal for study evaluations is not to provide a yes or no answer to the question but to generate knowledge, communicate uncertainty about conclusions and enable an informed discussion about knowledge gaps and possible actions to be taken.

### Literature search

An updated search of the relevant scientific literature was performed the final week of October 2015 in the Medline and Embase databases primarily relying on their hierarchical controlled-vocabulary thesauri. The concept of cancer (including carcinogenesis) was covered by selecting all records indexed to the most general cancer term, "Neoplasms" ("Neoplasm" in Embase), or to any of its narrower terms; 683 total Medline terms and 1002 in Embase. The cancer set was combined by Boolean AND with items indexed to either "Nicotine" or "Cotinine." In Embase, allowance also was made for items indexed to either "Nicotine N Oxide" or "Nicotine N' Oxide." No such inclusion was necessary in Medline, since that database maps the oxides to "Nicotine," modified by an "analogs & derivatives" sub-heading.

Since Medline makes titles and abstracts available before being fully indexed, a strategy such as the above must be supplemented by a "free-text" approach to pick up the mostly newer unindexed records. Thus, the "In-Process," "Epub Ahead of Print" and "PubMed-Not-Medline" file segments were queried for either of nicotine or cotinine and any of cancer?, carcino?, tumor?, tumor?, cocarcinogen?, neoplas?, oncogenic or oncogenesis (where? represents zero or more characters).

Using the above search methodology, 3138 database records were identified. One of the authors (MWF) read the title and abstract (as available) for each of these records and applied the inclusion and exclusion criteria (as detailed in the Section "Inclusion/exclusion criteria") to identify relevant studies for evaluation. This search strategy in combination with using secondary sources from publications and reviews (as described in the next paragraph) resulted in the identification of one publication for human studies and 75 publications for animal studies to be critically assessed and evaluated (Figure 1).

In addition to the process described above, one of the authors (H. J. H.) identified recent reviews that addressed the potential of nicotine to act as a carcinogen or as a modulator of carcinogenesis (Benowitz 2011; Impropio et al. 2011; Lee et al. 2011; Singh et al. 2011; Cardinale et al. 2012; Jensen et al. 2012; Schuller 2012; Hecht

2012a; Warren & Singh 2013; Grando 2014; Schaal & Chellappan 2014; Schuller 2014). These reviews as well as original studies were found with PubMed searches performed in January 2015, using keywords "nicotine AND cancer," and "nicotine AND carcinogen\*." Relatively old but relevant *in vivo* studies on nicotine and its metabolites were also discovered by checking earlier reviews (Larson et al. 1961; Schievelbein 1962; Levy & Martin 1989). All these reviews and original research publications were used as secondary sources to identify relevant published studies.

### Inclusion/exclusion criteria

The articles identified as potentially eligible for inclusion in the present review were examined and confirmed as in scope by one of the authors (H. J. H.) based on inclusion/exclusion criteria described in detail below and illustrated in Figure 1. In many cases, a single publication contained data from several relevant studies. For example, a single publication could contain results from using various strains of animals, various routes of nicotine administration or various kinds of cancer cells in xenograft experiments. The relevant studies present in a single publication are referred to as sub-studies. As a result, the 74 publications identified using animals contained 112 relevant animal studies or sub-studies (33 cancer causing and 79 modulating cancer). Thus, in the present review, 113 (sub-)studies (including one human study) were critically assessed for relevance and quality as well as evaluated for strength of evidence in categories such as human studies and animal studies including complete carcinogenesis and modulating carcinogenesis.

Studies included for evaluation are those in which nicotine, free base or salts, or the major metabolites of nicotine, cotinine or nicotine-*N'*-oxide (NNO), are administered. The half-life of nicotine is relatively short, especially in rodents, while the half-life of some of nicotine's metabolites, such as cotinine and NNO, are longer (Matta et al. 2007). Therefore, it seems plausible that, findings that appear to be related to nicotine may instead result from one or more of its metabolites. Accordingly, studies that investigate the potential carcinogenicity of cotinine or NNO exposure were identified and are included in the current review.

Studies in which nicotine delivery systems are used for exposure are included. As previously mentioned, nicotine delivery systems refer to products that contain nicotine as the only added active ingredient, that contain pharmaceutical grade nicotine and do not contain tobacco. Examples would include the NRT products listed in Table 1 as well as ENDS such as e-

cigarettes. Accordingly, studies investigating the potential carcinogenicity of NRT products in humans and animals were identified and are included in the current review. In contrast, no relevant studies using ENDS were identified or evaluated.

Studies that use any product that contains tobacco for nicotine exposure are excluded. Epidemiological studies on Swedish snus (a smokeless tobacco) are often used as an indirect measure of the potential carcinogenic effect of long-term nicotine use in humans (Benowitz 2011). However, for this review, exposure to nicotine *per se* and snus are not considered equivalent. They differ in that a snus user is exposed not only to nicotine extracted from this tobacco product but also exposed to compounds that may mask a potential carcinogenic effect of nicotine (Hecht et al. 1986; Hoffmann et al. 1987; Prokopczyk et al. 1987).

Pesticide products that contain nicotine in combination with other tobacco alkaloids or contain nicotine of unknown purity are excluded. Studies that investigate the use of non-nicotine compounds or products are also excluded. Examples would include tobacco-specific nitrosamines such as 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) or *N*-nitrosonornicotine (NNN), and tobacco alkaloids other than nicotine.

Studies that describe the use of carcinogenesis endpoints or the possibility of detecting such are included. Examples of such endpoints include cancer diagnosis (human studies), gross pathology assessment, tissue histopathology analysis, tumor-related characteristics such as tumor size or volume, vascularization or metastasis. Studies identified in the literature search that do not include such endpoints are excluded from evaluation. Common non-carcinogenesis endpoints observed include those found in studies investigating metabolism, dependence and receptor activity (nAChRs).

Studies that are described in publications that are reviews, commentaries or opinions are not evaluated in this review. Only publications describing original research studies in some detail are included in this review.

Studies that are not conducted in humans or animals (e.g., *in vitro*) are excluded from evaluation in this review. Seventy-four relevant animal publications (whose studies met the inclusion criteria above) are assigned to one of the two subtopic categories, cancer causing or modulating cancer (Figure 1). Cancer causing studies are those that investigate whether nicotine acts as a complete carcinogen. In these studies, carcinogenesis is followed in animals during long-term exposure to nicotine alone. The second subtopic category of animal studies comprises those evaluating the modulating (stimulating) effect of nicotine on carcinogenesis

induced by other sources. Relevant modulating carcinogenesis studies are placed in one of the two subcategories depending on the source of carcinogenesis. These are a chemical, physical or transgenic source or the implantation of cancer cells (xenograft source).

**Critical assessment of relevance and quality of studies**

The *in vivo* studies reviewed differ in various aspects of study design, conduct and reporting. Thus, it is challenging to compare studies as well as to determine the strength of evidence for each of the studies that have passed the inclusion criteria in order to evaluate the potential carcinogenicity of nicotine. To facilitate this evaluation, certain criteria, based on current international guidelines for carcinogenicity testing (Organisation for Economic Co-operation and Development 2009), were used for judging relevance and quality of studies. Both criteria were combined to derive a score for the adequacy of a study for the purpose of this evaluation. Five design criteria on study relevance, including route of administration, group size, dose response, daily dose, duration of exposure as well as quality were scored separately as plus (+) or minus (–) and documented in the supplementary material (Supplementary Tables 1–3). If information was lacking, the study was assigned a minus score. Alternative approaches to judge study relevance and quality have been published. For instance, the Klimisch scores (Klimisch et al. 1997) were not considered discriminative enough for the current evaluation. This approach relies heavily on generally accepted international guidelines

**Table 3.** Adequacy evaluation criteria for individual animal studies on the potential carcinogenicity of nicotine.

Category	Adequate study parameters
Route of administration	Inhalation, oral, dermal
Group size	50 per sex (100 of single sex)
Dose response	Three (or two) dose levels
Daily dose (average)	Eliciting signs of toxicity, or ≥1 mg/(kg × d)
Duration of exposure	≥18 months (complete carcinogen studies) Any duration (modulating carcinogenesis studies)
Quality (subjective)	e.g., Nicotine biomonitoring, body weight data

- Notes:
- (1) Adequacy criteria for group size, dose response, and study duration were derived from the carcinogenicity study design guidance provided by the Organisation for Economic Co operation and Development (2009). Other adequacy criteria were subjectively set by the authors.
  - (2) Adequacy was scored with plus (+) or minus (–). If information was lacking, minus (–) was also applied.
  - (3) Plus (+) scores of a study were totaled for an overall adequacy score. The maximum plus (+) score is 6 (studies on complete carcinogenesis) or 5 (modulating studies), with >2(+) representing a high adequacy score and ≤2(+) representing a low adequacy score.

and/or Good Laboratory Practice and few studies in our review were conducted approaching such guidelines.

Our adequacy evaluation criteria are listed in Table 3 and briefly explained as the following: adequate routes of administration were those that corresponded to the use of nicotine delivery systems in humans, i.e., inhalation, dermal and oral (Organisation for Economic Co-operation and Development 2009).

For the first category of studies, group sizes of approximately 100 or more (or 50 per sex) were considered adequate (Organisation for Economic Co-operation and Development 2009). Optimally, a dose-response relationship on the basis of at least three dose groups should be targeted (Organisation for Economic Co-operation and Development 2009), but each attempt to have more than one dose group was honored as adequate.

Average daily doses were calculated or estimated as a common denominator. Because this calculation is imprecise in view of the rapid nicotine metabolism in most laboratory animals, the actual dosing regimen was also provided in the Supplementary material, which lists the various studies in detail (Supplementary Tables 1–3). The highest dose level in the carcinogenicity studies should be selected to elicit some evidence of toxicity (Organisation for Economic Co-operation and Development 2009). Thus, any sign of nicotine-related toxicity, such as body weight or survival effects, was honored as indicative of a sufficiently high dosing and considered adequate. There might have been very acute and transient toxic reactions to nicotine injection, which were also honored here, although the same average daily dose given continuously, e.g., via the drinking water, might have avoided such toxic response. Another criterion of adequacy related to dosing or exposure was the assumption that the experimental nicotine exposure relative to body weight was similar or higher than in a user of nicotine delivery systems. For NRT, it is recommended that nicotine gum users consume no more than 24 units containing 4 mg nicotine each per day, while for nicotine inhaler users, not more than 16 units containing 10 mg nicotine each per day is recommended and sublingual tablet users can use up to 24 units containing 2 mg of nicotine each (Schneider et al. 2001). Thus, the upper limit of exposure to nicotine from NRTs can be estimated to be approximately 1 mg/(kg × d). Doses at this level or above were also considered adequate. The assessment of nicotine doses from experimental studies is hampered by the fact that quite often it was not stated whether doses were given in terms of pure nicotine or any salt and whether a racemic mixture or the pharmacologically active *S*(–)-enantiomer was used. If not stated otherwise, the data are interpreted as pure

(–)-nicotine, which may lead to erroneous overestimates of nicotine doses of up to six-fold.

Study durations of ≥18 months were honored as adequate according to guidelines for assessing complete carcinogenesis (lower range of acceptable study durations selected for inclusion of studies with susceptible spontaneous or transgenic strains; Organisation for Economic Co-operation and Development 2009). For cancer-modulating studies, study duration was not a useful adequacy criterion. In many of these studies, the initial inducer of carcinogenicity was administered in a way that led to rapid tumor development. Therefore, animals in these studies were exposed to nicotine for relatively short periods of time, if these time periods were considered sufficient to induce cancer by the initial treatment alone. Because cancer growth was apparently easily observed in most of these studies, as a consequence of the initial treatment, any duration of nicotine exposure was honored as adequate for modulating carcinogenesis studies.

A final score was given based on a subjective evaluation of study quality. This included the availability of body weight or nicotine biomonitoring data, which were thought to at least improve the comparison of studies with similar design.

In order to achieve a comprehensive overview, no study was excluded from evaluation because it failed a certain study adequacy criterion. Rather, all studies that passed the inclusion criteria were evaluated. For assessing the strength of evidence for the studies evaluated, an overall adequacy score was determined by totaling the individual plus values for each individual sub-study. This approach gave all adequacy criteria the same weight. However, for practical reasons, only studies (or parts thereof, i.e., sub-studies) with high-adequacy scoring (with an overall score >2) were discussed in detail in the main body of the review, while narratives regarding studies or sub-studies with low-adequacy scoring (with an overall score ≤2) were placed in the Supplementary material (Supplementary Table 4). Scoring results were also used to roughly divide studies into two categories or tiers in other assessments (Goodman et al. 2014), but ranking of studies was avoided. Here, the overall results of studies with low-adequacy score were compared with those observed in high-adequacy score studies within the same subsection, to detect potential biases when stratifying by study adequacy.

### **Strength of evidence evaluation and classification**

The evaluation and the integration of scientific evidence as well as strength of evidence classification (for human,

animal, complete carcinogen, modulating carcinogenesis studies) are a matter of facilitated professional judgment, reflecting conclusions derived from evaluating relevant studies individually and collectively. The term “facilitated” refers to professional judgment that is guided by key factors or criteria for drawing conclusions from scientific studies (Rhomberg et al. 2013). The use of such criteria is described below. Key factors or criteria considered in the present review for evaluating and integrating scientific evidence were adapted from numerous sources and are described in brief below (Hill 1965; Goodman et al. 2013; Rhomberg et al. 2013). Criteria for evaluation and integrating evidence include consideration of the reproducibility, reliability and strength of the observed carcinogenic response, the presence of a dose (exposure)-carcinogenic response relationship, the timing (temporal relationship) and specificity of the carcinogenic response following nicotine exposure, and the dose and route of administration that is relevant to human nicotine exposure (nicotine delivery systems).

The framework described above uses an approach adapted from Bradford Hill and US Environmental Protection Agency (Hill 1965; Rhomberg et al. 2013). This approach was modified taking into account that conclusions in the present review did not consider mechanism of action data (biological plausibility) and limited information is available for long-term nicotine exposure in humans (lack of coherence). Therefore, it is important to remember that the strength of evidence conclusions and classifications in this review are a generalization. That is, we recognize the inherent difficulty in applying specific animal study results to arrive at conclusions for a more general study question (Rhomberg et al. 2013).

A thorough discussion of the strengths and weaknesses (based on the above criteria) of the relevant studies for each topic is provided in this review. Using our adequacy scoring system, less ideal studies (low-adequacy score) were not rejected outright but were summarized briefly as a narrative for each topic area (a more detailed evaluation of each study is found in the Supplementary material). The conclusions from the low-adequacy scored studies were then compared with the more detailed narrative and conclusions from the high-adequacy scored studies, again for each topic. Finally, the reasoning for the overall strength of evidence conclusion and classification was discussed in the present review for each topic (human, animal, cancer causing and cancer modulating studies).

The strength of evidence classifications used in the present review were adapted and modified from the Evaluation of Carcinogenic Risks outlined by the

International Agency for Research on Cancer (IARC) (International Agency for Research on Cancer 2007). A major modification to the IARC strength of evidence assessment is the separation of the IARC classification “evidence suggesting lack of carcinogenicity” into two classifications: “limited evidence suggesting a lack of effect” and “sufficient evidence of a lack of effect.” With this revised classification in place, the strength of evidence conclusions are balanced. A conclusion and classification can be neutral (inadequate evidence) or can be deemed limited or sufficient in both directions, for a carcinogenic effect or for a lack of a carcinogenic effect. Strength of evidence classifications used for evaluating human and animal studies were as follows:

- *Sufficient evidence*: Conclusive or highly suggestive studies are available for an association between nicotine exposure and either a lack of carcinogenic effect or a carcinogenic effect.
- *Limited evidence*: The evidence from available studies is indicative of an association between nicotine exposure and either a lack of carcinogenic effect or a carcinogenic effect. Conclusive studies are missing.
- *Inadequate evidence*: The available studies are of insufficient quality or consistency to permit a conclusion regarding an association between exposure to nicotine and carcinogenesis. Only conflicting or incomplete evidence is available.

We believe that one strength of the classification system described above is that it provides a balanced and symmetrical distribution for strength of evidence conclusions. On both sides of a neutral conclusion (inadequate evidence), there exists the same possible classification (sufficient or limited evidence) for either a carcinogenic effect or the lack of an effect. Similarly, Rhomberg et al. (2011) supported a “two-pan balance” system for determining the weight of evidence as a more satisfactory means of drawing conclusions from an array of observations. These investigators suggested that many classification systems use “a single scale showing how much evidence in accord with a conclusion can be accumulated.” We believe that the IARC (International Agency for Research on Cancer 2007) and equipoise (Goodman et al. 2013) classification systems suffer from this limitation. Both systems favor observations demonstrating a positive effect, with only one availability category for a lack of an effect (sufficient evidence). Obviously, providing sufficient evidence for a lack of an effect is very difficult to accomplish especially in light of the fact that negative findings often go unpublished. Another strength is our classification system (sufficient, limited, and inadequate evidence) provides a clear

communication that is easily understood, both from an overall conclusion point of view as well as the reasoning behind the message. Other frameworks using an equipoise classification system (e.g., equipoise and above or below equipoise), for example, are not easily understood.

As previously mentioned, a limitation of our strength of evidence conclusions is the absence of mechanistic data as well as little information in humans. Thus, our classification system is not meant to determine conclusions for a causal relationship between nicotine exposure and carcinogenesis.

### Evidence from human studies

Epidemiological and clinical studies on the cancer risk associated with using nicotine delivery systems were identified and reviewed. One NRT study was identified as relevant and was critically evaluated. No other cancer-related studies with users of other nicotine delivery products (such as ENDS) were found.

#### *Epidemiological studies with nicotine replacement therapy (NRT) use*

The Lung Health Study investigated the cancer risk from using NRT products. This study prospectively investigated surveillance data on 3320 intervention participants who were enrolled in this study for 5 years and then followed up for 7.5 years (Murray et al. 2009). Nicotine gum use and smoking were determined by self-reporting, although the nicotine exposure from gum use may have been quite accurate as it was supplied for free to the participants of the study for the full 5 years. Most participants used either NRT or cigarettes, rather than using both concurrently. Using Cox proportional hazard regression analysis, the NRT alone was not a significant predictor of lung cancer [hazard ratio (HR) 1.02, 95% confidence intervals 0.95–1.09], while continued smoking was predictive [HR 1.08 (1.01–1.16)]. Neither NRT use nor continued smoking was significant predictors for all cancers and for gastrointestinal cancers in particular (including oral cancer). Survival from any diagnosis of cancer was the same between users of NRT and non-users. Most importantly, survival without any diagnosis of lung cancer was significantly higher for those participants below the median cigarette exposure during the study compared to those above the median level (determined in pack-years). There are a number of serious limitations regarding the interpretation of this study that were identified by the authors. First, the 5-year study duration and the follow-up period of 7.5 years are not considered long enough for lung cancer to

develop. In addition, the total number of lung cancer cases in the study (morbidity and mortality) was only 75. Finally, the daily nicotine exposure in the NRT user group was approximately 2 mg (average of 2 gums per day with 2 mg nicotine per gum, assuming 50% extraction). Considering an appreciable first-pass effect upon oral nicotine exposure (see Section “Comparative toxicokinetics”), the estimated nicotine exposure in this study is approximately one order of magnitude below that observed for users of nicotine delivery products (Table 1).

In summary, this study provided no evidence for an effect of NRT use on cancers of the lung, the gastrointestinal tract or overall. This one study provides inadequate evidence for an association between nicotine exposure and the presence of or lack of a modulating effect on carcinogenesis following smoking cessation.

### Conclusion on human studies

There is only one epidemiological study on the long-term use of NRT after smoking cessation, and this study provided no evidence for an effect of NRT use on cancers of the lung, gastrointestinal tract, or overall. This study, however, was relatively short given the reported 20–30 year latency period for lung cancer. Longer-term prospective epidemiological studies are required to support the hypothesis that nicotine does not cause cancer by itself or stimulate carcinogenesis. This would include surveillance studies after smokers switched to NRTs or ENDS as well as studies on users of these products without prior use of conventional tobacco products. Overall, for human studies (NRT use), there appears to be inadequate evidence for an association between nicotine exposure and the presence of or lack of a carcinogenic effect due to a limited number of studies.

### Evidence from animal studies

#### *Comparative toxicokinetics*

Because there is little information from studies in humans, laboratory animal studies are important in evaluating the carcinogenic potential of nicotine, at levels found in users of nicotine delivery systems. The kinetics of nicotine absorption, distribution and metabolism are relevant for its pharmacological action (Benowitz et al. 2009), but also must be considered for the evaluation of its toxic activity, e.g., when comparing different routes of administration in various species and when extrapolating to the human nicotine user.

The time course for systemic nicotine distribution is fastest after inhalation (within seconds), intermediate for

oral uptake and relatively delayed after dermal exposure (lag time of 1 h) (Benowitz et al. 2009). Once absorbed, nicotine is widely distributed in the body. As a consequence of the first-pass effect, only 30% of orally administered nicotine can reach systemic circulation (Matta et al. 2007). After inhalation or intravenous (i.v.) exposure, however, the first-pass effect of hepatic metabolism is avoided. The plasma half-life of nicotine in humans is approximately 2 h (Hukkanen et al. 2005). At an experimental dose of 1 mg/kg in rats and mice, half-lives of 0.75–1.6 h (Kyerematen et al. 1988; Schepers et al. 1993; Matta et al. 2007) and 6–9 min (Petersen et al. 1984; Siu & Tyndale 2007) were reported, respectively. These differences in elimination half-lives mirror differences in the rates and also patterns of nicotine metabolism among species. Thus, the route and mode of administration (e.g., injection versus continuous exposure) and the choice of species used for a study will determine differences in local and systemic exposures of nicotine and its metabolites that may lead to toxic and carcinogenic effects. Animal studies for the investigation of the potential carcinogenicity of nicotine were, therefore, sorted according to the route of administration used in the various studies reviewed herein.

Several nicotine metabolites have longer half-lives than the parent compound, such as cotinine in human smokers (16 h, Benowitz et al. 2009), rats (3 h, Schepers et al. 1993) and mice (25–50 min, Siu & Tyndale 2007), and have, therefore, been monitored as surrogates for nicotine exposure.

Figure 2 provides a schematic overview of the average range of levels for nicotine doses in users of nicotine

delivery systems and the respective nicotine and cotinine levels in blood (based on the values from Table 1). These data can be used to compare nicotine exposures in animal studies based on doses relative to body weight or on blood and urine levels, as available (Figure 2).

For instance, to achieve the same systemic nicotine concentration, higher nicotine doses relative to body weight have to be administered to rodents (especially mice) in comparison to humans. At drinking water doses of 20 mg/(kg × d) or higher, blood nicotine and cotinine levels can be achieved in mice similar to those in users of nicotine delivery systems (Table 1).

In animals, to maintain a nicotine blood level throughout the day that mimics the diurnal changes commonly seen in users of NRT or ENDS, inhalation or the oral administration of nicotine via the drinking water or the diet appear most suitable.

### Potential of nicotine to cause cancer in animals

Studies aimed at evaluating the carcinogenic potential of nicotine can be divided into two categories: studies or study parts (sub-studies) with exposure to nicotine alone and studies or sub-studies with exposure to nicotine in combination with other exposures. The intention of reviewing the first category of studies is to evaluate the potential of nicotine to cause cancer, i.e., whether nicotine acts as a complete carcinogen. The intention of reviewing the latter category of studies is to evaluate the modulating effect of nicotine on the carcinogenic

**Figure 2.** Overview of nicotine biomonitoring data in mouse and rat studies (various shaped arrows). Data referring to human exposure and blood nicotine levels are presented as a black bar indicating the range of data presented in Table 1 (users of nicotine delivery systems). For species comparison, mouse data are shown from studies with oral administration via the drinking water (red color: Pietilä et al. 1995; Sparks & Pauly 1999; Grabus et al. 2005; Arany et al. 2011; AlSharari et al. 2013), s.c. osmotic minipump (brown color: AlSharari et al. 2013) and feeding (violet color: Theophilus et al. 2012). Rat data are shown from nicotine inhalation (black color: Werley et al. 2014), continuous s.c. administration via minipump (dark blue color: Cheng et al. 2005), and feeding (blue color: Theophilus et al. 2012).

**Table 4.** Reported findings of relevant studies for evaluating the potential of nicotine to act as a complete carcinogen.

Route/adequacy scoring	Number of (sub)studies	Positive*	Negative*	Labs†
Inhalation				
Total	1	0	1	1
High score	1	0	1	1
Low score	0	0	0	0

Total	14	2	3	12
High score	1	0	1	1
Low score	13	2	2	11

To facilitate comparisons, the (sub)studies were grouped into high and low adequacy scoring studies with overall scores subjectively set to  $\geq 2$  and  $\leq 2$ , respectively.

\*As judged by the authors of the respective studies, where "positive" indicates stimulating carcinogenesis and "negative" indicates a lack of carcinogenic effect.

†Number of different laboratories contributing studies.

‡The two positive studies (both s.c.) were those with the longest exposure period. Many shorter but still chronic studies in this category were not planned as carcinogenicity studies and were, therefore, often not judged by the respective authors as positive or negative for carcinogenesis. This resulted in a total number of studies that was higher than the sum of studies reported as positive or negative by the authors.

potency of these other exposures (Section "Potential of nicotine to modulate carcinogenesis").

In the first category, several animal species were exposed to nicotine using different routes of administration in studies published over the past 100 years. A summary of reported conclusions from all reviewed studies on the potential of nicotine to act as a complete carcinogen is given in Table 4. A more detailed description of high-adequacy score studies is provided in the section below. A description of low-adequacy score studies as well as a more detailed overview of each study evaluated in this category is provided in the supplementary material (Supplementary Tables 4 and 1, respectively). At the end of the current section, both high and low-adequacy score studies are discussed in aggregate, and a conclusion on this part of the review is provided.

### Inhalation exposure

Waldum et al. (1996) conducted a 24-month inhalation study in Sprague–Dawley rats with nicotine exposure for 20 h/d, 5 d/week at a reported nicotine concentration of 0.5 mg/m<sup>3</sup>. A nicotine dose of 0.4 mg/(kg × d) can be estimated on the basis of an average body weight of 300 g/rat, a standard respiratory minute volume of 0.2 l (estimated according to Alexander et al. 2008) and

assuming full retention of the inhaled nicotine (Feng et al. 2007). No food was available during the whole-body nicotine exposure. Plasma nicotine levels were found to exceed the range found in users of nicotine delivery products (Table 1) by several folds. In this study, the determination of blood nicotine levels seems to be appropriate for comparison to users of nicotine delivery systems due to the long daily nicotine exposure, which probably resulted in a relatively stable steady-state concentration. The body weight of the nicotine-exposed rats was approximately 5% lower than that of the sham-exposed rats (Waldum et al. 1996) indicative of an effective nicotine exposure level. There was only one dose level, but this dose level was in an effective range. From the initial animals in the nicotine and sham control groups (68 and 34 rats, respectively), several were used for regular necropsies during the study. Thus, only 22 and 7 rats, respectively, were available for the final necropsy, which included examination of the brain, lungs, gastrointestinal tract, liver, kidneys and ovaries for tumors. For the rats undergoing necropsy during the course of the study, 36% and 24% of the nicotine and control groups, respectively, had tumors, such as age-related mammary tumors, which were found in both groups. Historical control data from this laboratory are not available, but mammary fibroadenomas in female Sprague–Dawley rats are spontaneous tumors frequently observed at the end of cancer studies (Dinse et al. 2010). Some tumor types were only found in nicotine-exposed rats, i.e., tumors of the anterior pituitary gland (8% incidence), ovary (5%) and skin (2%). In addition, two metastases of unknown origin were found in nicotine-exposed rats. None of these tumor incidences was statistically significantly different between nicotine and sham-exposure groups. Moreover, in historic controls, tumors have frequently been observed in various parts of the pituitary gland (between 1% and 39%) and occasionally also in the ovary (up to 0.6%), and skin (up to 1.7% incidence, Dinse et al. 2010). No lung tumors were detected in either group. Additionally, lung neuroendocrine hyperplasia was investigated, and no effect by nicotine was found. The authors of this study, which was a high-adequacy scoring study, concluded that they "did not find any tumorigenic effect of nicotine on any organ in the body."

### Oral administration

Wilson et al. exposed Albino rats to nicotine sulfate, nicotine tannate or nicotine bentonite via their food in order to investigate body weight and organ microscopic damage (Wilson & DeEds 1936; Wilson et al. 1938). For up to 10 months, the rats were exposed to four doses of

nicotine sulfate at levels of 0.006–0.05% in the diet. These levels corresponded to doses of approximately 4 mg/(kg × d) to 33 mg/(kg × d). A no-observed adverse effect level of 4 mg/(kg × d) was reported based on the retarded body weight development and lower food consumption compared with control. Microscopic examination revealed that organs (liver, spleen, kidneys, lungs, adrenals, heart, testes, thyroid and pancreas) from nicotine-treated rats showed negligible structural difference from organs obtained from control animal (nicotine-free feed). This high-adequacy scored study is characterized by a suitable dose–response assessment, but it is hampered by the relatively short duration. Group sizes were not reported.

Toth (1982) exposed Swiss mice in sufficiently large groups for their lifetime to 0.5 and 0.7 mg/ml nicotine via the drinking water. For the group exposed to the high concentration, the author reported daily doses of 4.3 and 5.3 mg of nicotine hydrochloride for female and male mice, respectively, which translates to average nicotine doses of approximately 150 mg/(kg × d) assuming a body weight of 25 g. Due to higher water consumption, the daily dose per mouse in the low-concentration group was only minimally smaller than in the high concentration group. Surprisingly, no toxicity, in particular, no impact on body weight development or survival, was reported at these doses, although the dose reported clearly exceeded that of other drinking water studies using mice. Histopathological examination of the liver, spleen, kidneys, bladder, thyroid, heart, testes, pancreas, ovaries, brain, nasal turbinates and lungs (at least four lobes) was performed but findings were not reported, except for tumor incidences. No increase in tumor incidence due to nicotine exposure was observed, in particular in lungs, which had a background tumor incidence of approximately 15%. The Swiss strain of mice is genetically predisposed to a relatively high lung cancer susceptibility (Manenti & Dragani 2005). The author of the study, which received the highest adequacy score in this review, concluded that nicotine was “not carcinogenic under the experimental conditions.”

Murphy et al. (2011) exposed A/J mice to 0.2 mg/ml nicotine hydrogen tartrate (NHT) for 11 months via the drinking water. Water consumption was significantly lower in nicotine-exposed mice compared with sham-exposed mice, but there was no indication of dehydration. Body weights were not reported. Based on the reported weekly water consumption of 15 ml and an estimated body weight of 25 g, a daily nicotine dose of 6 mg/kg could be calculated. Plasma and urinary nicotine and cotinine levels were also reported. While the plasma cotinine level of mice was below that observed

in humans, the urinary cotinine level found in the mice of this study exceeded that normally found in humans. No significant effect by nicotine on lung tumor multiplicity and size was observed, although there was an incidence of 15% (2/15 mice) adenocarcinomas in the nicotine-exposed group compared with the sham control with none. A similar pattern of numerically higher incidences and multiplicities of adenocarcinomas in the nicotine- versus sham-exposed mice was also observed in parallel groups that were pretreated with the tobacco-specific N-nitrosamine NNK. The A/J mouse is a strain susceptible to lung carcinogenesis, and thus, in this particular case, a study duration of 11 months should be sufficient for examining potential carcinogenic effects in this particular tissue (Stoner & Shimkin 1982); however, a group size of 19 is relatively small.

Hermann et al. (2014) exposed C57/Bl6 mice for 18 months to nicotine via the drinking water at a nominal dose of 20 mg/(kg × d). The authors were particularly interested in mechanisms of pancreatic carcinogenesis. No effect on the area of pancreatic intra-epithelial neoplastic lesions by nicotine was observed. No other neoplastic findings were reported. This sub-study was conducted in parallel to a study using transgenic mice and reportedly was only intended to confirm earlier reports of no effects by nicotine on pancreatic tumorigenesis; on its own right, it suffered from a very small group size ( $n=3$ ) but otherwise received a high-adequacy score.

Nishikawa et al. (1992) investigated the potential of nicotine to induce pancreatic carcinogenesis. Nicotine was administered to female Syrian Golden hamsters for 9 months at an estimated dose of 2.5 mg/(kg × d) via the drinking water ( $n=30$ ). The pancreas was carefully examined in serial sections of four anatomical lobes. In addition, the spleen and the duodenum were grossly examined. No neoplastic or preneoplastic lesions were detected in the pancreas.

### *Subcutaneous administration*

Thompson et al. (1973) administered nicotine (as a base) s.c. to male Fischer rats for up to 22 months at a daily dose of 1 mg/kg. Nicotine was administered in a gelatin matrix with the intention to prolong the absorption from the injection site and achieve a rather sustained nicotine distribution. The nicotine exposure was high enough to elicit a significant decrement in the body weight development of the rats (approximately 15% at maximum, which is generally considered acceptable for valid carcinogenicity studies). Starting group sizes were 38 for the nicotine treatment group and 10 for the vehicle control group, but mainly due to technical reasons, only

28 and six rats remained for the final dissection. The spleen, liver, adrenals, vertebra, lymph nodes, lungs, heart, kidneys, thymus, testes, anterior pituitary gland, skin, trachea, renal artery and aorta were routinely examined in the euthanized animals. No consistent differences in general pathology, which was described to be typical for aged rats of this strain, were found between the control and the nicotine-exposed groups. In the control group, two tumors were discovered, an adenocarcinoma of the lung and an adenoma of the anterior pituitary gland resulting in an incidence of 33%. Within the nicotine-exposed group, there were nine tumors present in eight rats resulting in an incidence of 29%. These tumors included three instances of pheochromocytoma, four cases of epidermoid carcinoma of the skin, one leukemia and one fibrosarcoma. The authors noted that all the tumors found are frequently observed in aged rats. In particular, pheochromocytomas indeed occur at rather high incidence in male rats (Greim et al. 2009). The only statistically significant difference in histopathology was the incidence of Leydig cell hyperplasia, which occurred in 89% of the nicotine-exposed and 66% of the control rats. The authors noted that the etiologic significance of the observation is unclear. Apparently, Leydig cell tumors are not commonly observed in other studies with this strain of rat and of similar duration. Overall, this negative study is characterized by its sufficient dosing and duration and the broad scope of organs and tissues examined, but it only had one dose level of nicotine and the group sizes were small.

### *Low-adequacy score studies*

Relevant studies with low-adequacy scores using intra-tracheal installation (Yokohira et al. 2012), oral administration (Schoental & Head 1953; Truhaut & De Clercq 1961), dermal application (Schoental & Head 1953), s.c. injection (Staemmler 1935, 1936; Yun & Kim 1938; Hueper 1943; Eränkö et al. 1959a, 1959b; Thienes 1960; Schuller et al. 1995; Galitovskiy et al. 2012), i.v. injection (von Otto 1911; Kosdoba 1930) and i.p. injection (Schmähl & Habs 1976) were identified and evaluated. These studies are described in the Supplementary material as a narrative (Supplementary Table 4) and as an entry in the evidence table in the Supplementary material (Supplementary Table 1).

### *Discussion of aggregate evidence*

**High-adequacy score studies.** Seven studies were identified with high-adequacy scoring and each varied widely in study design and quality. Overall, the greatest

weaknesses often included the lack of dose-response analyses, a lack of sufficient group sizes, a lack of sufficient exposure duration and the lack of sufficient tissue histopathological analyses. However, all these studies were negative with regard to any potential carcinogenic effect of nicotine. These studies were conducted in numerous laboratories with three species (i.e., rats, mice and hamsters) and three different routes of administration, including the relevant inhalation and oral exposure routes. The highest adequacy scores were obtained by the two major dedicated carcinogenicity studies that were judged negative (lack of carcinogenic effect) by the authors (Toth 1982; Waldum et al. 1996). The negative study by Toth (1982) came closest to a study design matching current bioassay guidelines.

**Low-adequacy score studies.** Sixteen low-scoring studies were reviewed in this section and were predominantly considered negative (lack of carcinogenic effect) by their authors, with two exceptions using s.c. nicotine administration.

One exception relates to adrenal medulla adenocarcinomas or pheochromocytomas reported after s.c. nicotine administration to rats (Staemmler 1935). This effect was not dose dependent, and it was not observed again in other studies of similar design that were conducted in rats, mice, Guinea pigs and rabbits (Kosdoba 1930; Eränkö et al. 1959a, 1959b; Thienes 1960; Thompson et al. 1973), with one exception, i.e., a 22-month s.c. nicotine administration study in which three rats were observed in the nicotine group and none in the control (not statistically significant, Thompson et al. 1973). In particular, the Thienes (1960) and Eränkö et al. (1959a, 1959b) studies were performed in response to the findings reported by Staemmler (1935), but the carcinogenic effect could not be reproduced. The occurrence of pheochromocytomas seems to be related to disturbances in catecholamine synthesis, which may indeed be the case in the nicotine exposure studies (Greim et al. 2009). A morphological effect of nicotine on adrenals might seem plausible, as nicotine can stimulate the release of corticosterone and catecholamines from the adrenal cortex and medulla, respectively, and hypertrophic adrenals were indeed described for i.v.-treated rabbits (Kosdoba 1930). However, an effect on adrenals was not reported in 90-d nicotine feeding studies with rats and mice at doses of 6 and 120 mg/(kg × d), respectively (Theophilus et al. 2012). In general, the relevance of pheochromocytomas in rat carcinogenicity studies for human risk assessment was questioned (Greim et al. 2009).

The second exception was the report that rhabdomyosarcomas and leiomyosarcomas were observed after

s.c. nicotine administration to A/J mice for 5 d/week for 24 months (Galitovskiy et al. 2012). This study had small group sizes, and no statistical tests were performed. The development of spontaneous rhabdomyosarcomas was also observed in other studies using this mouse strain: Rhabdomyosarcomas at the hind legs and lower back were described to be rather frequent spontaneous tumors in A/J mice (34% incidence, Landau et al. 1998). In a chronic mainstream smoke inhalation study in A/J mice, rhabdomyosarcoma incidences of 27% and 43% in female and male control mice were observed, respectively, which tended to decrease with increasing mainstream smoke and thus nicotine exposure concentrations (Stinn et al. 2013).

Leiomyosarcomas have not been reported as a consequence of nicotine administration in other studies, and this finding would need to be reproduced in a more carefully designed study with a more appropriate route of administration. Interestingly, the authors reported only one mouse with pulmonary adenoma. The incidence of lung tumors after 24 months observed in this study is surprisingly low, as most other studies in A/J mice showed 100% incidence at this age (e.g., Stoner & Shimkin 1982).

In principle, the overall results of the low-adequacy studies agree with those of the high-adequacy studies, i.e., they do not suggest that nicotine is a complete carcinogen.

**Comparative evaluation by dose.** For a comparative evaluation, both high and low-adequacy studies were considered. The doses used in the various studies cover a relatively broad range for rats [0.3–33 mg/(kg × d)] and mice [1–150 mg/(kg × d)]. The doses used are similar or higher than those found for users of nicotine delivery systems. For example, in the lifetime mouse study conducted by Toth (1982), the dose of nicotine administered via drinking water exceeded by two orders of magnitude that reported for human exposure following nicotine use (relative to body weight). The lifetime inhalation study (Waldum et al. 1996) reported blood nicotine levels beyond those reported for human users of nicotine. Both the Toth (1982) and Waldum et al. (1996) studies reported the lack of nicotine-induced carcinogenicity. The most recent mouse study, which was reported as positive by their authors, used the lowest s.c. nicotine dose in this category (Galitovskiy et al. 2012), shedding additional doubt on the findings reported. A rat s.c. study with a similarly low apparent daily dose of nicotine for 22 months but with a pronounced nicotine-related body weight effect was negative for carcinogenesis (Thompson et al. 1973).

Nicotine concentration in body fluids may not be the best marker for comparing nicotine exposure from bolus injections due to the rather rapid and species-dependent clearance as well as the lack of standardizing sampling periods relative to nicotine administration. The only nicotine inhalation study available, however, exposed rats for 20 h/d, so the reported plasma nicotine value of 130 ng/ml most likely represents a stable, steady-state concentration (Waldum et al. 1996). However, the daily dose of 0.4 mg/(kg × d), estimated on the basis of the nicotine concentration in the aerosol and on certain assumptions of respiratory minute volume and body weight, does not fit the reported nicotine plasma level in comparison to other rat studies with sustained nicotine exposure (Figure 3). In a 90-d mainstream smoke nose-only inhalation study (6 h/d) in rats with a nicotine concentration of 13 mg/m<sup>3</sup> in the aerosol, a daily dose of 3.5 mg/kg can be estimated for the same strain and sex of rats using the same assumptions as above, which resulted in an average serum nicotine concentration of 280 ng/ml (Gaworski et al. 2008). In any case, the plasma nicotine value determined in the nicotine inhalation study (Waldum et al. 1996) most likely reflects a higher nicotine uptake than the estimated inhaled dose. As this study was conducted in a whole-body-exposure mode, nicotine deposited on the cage surfaces and the fur of the rats, which, as a consequence of self-grooming, can lead to several folds higher overall doses, as assumed from smoke inhalation studies (Mauderly et al. 1989; Haussmann et al. 1998). Based on the plasma nicotine values reported, the dose in this nicotine inhalation study (Waldum et al. 1996) appears to be sufficiently high to exceed human exposure from nicotine use and no carcinogenic potential was detected.

An average nicotine plasma level of 0.4 ng/ml was reported from a negative drinking water study in mice (Murphy et al. 2011), which is low, given the estimated dose of 6 mg/(kg × d) based on water consumption and body weight (Figure 3). In plasma, 19 ng/ml cotinine level was determined on average (Murphy et al. 2011). Both the nicotine and cotinine plasma levels reported are relatively low compared to those in human nicotine users (Figure 2). Urinary nicotine and cotinine concentrations of 1300 ng/ml and 4400 ng/ml, respectively, were also reported in this study, which are similar to and exceeding those found in users of nicotine delivery systems, respectively (Table 1 and Figure 2).

### Summary of the evidence

The high-adequacy score studies were consistently negative (absence of a stimulating effect on carcinogenesis). The statistical power of only a few of the

**Figure 3.** Overview of nicotine biomonitoring data in mouse and rat studies investigating potential nicotine-mediated carcinogenesis. Data (indicated by arrows) were generated in a rat inhalation study (Waldum et al. 1996) and in mouse studies with exposure to nicotine via drinking water (Wong et al. 2007; Maier et al. 2011; Murphy et al. 2011; Hermann et al. 2014; Li et al. 2015), via continuous s.c. administration (Hao et al. 2013), via i.v. administration (Li et al. 2015) and via patch and i.p. administration (Davis et al. 2009). Nicotine doses and nicotine and cotinine levels in blood and urine from users of nicotine delivery systems such as NRT products or ENDS are illustrated as black bars (blood) or diamonds and bars (urine) indicating the range of concentrations (from data presented in Table 1). Positive (cancer stimulating) and negative studies are characterized by red and green colors, respectively.

negative studies seemed to be sufficient, though. The finding of adrenal medulla adenocarcinoma in one low-adequacy study was not dose dependent and inconsistent with the results of other studies, although this type of effect might seem to be coherent with non-neoplastic effects of nicotine described in a few studies, i.e., adrenal hypertrophy. The findings of rhabdomyosarcomas and leiomyosarcomas in A/J mice injected with nicotine found in a low-adequacy score study was inconsistent with other studies, had a low strength of association (no statistical tests performed), and the low number of age-related spontaneous lung cancer cases was incoherent with historic controls of this strain of mice. As discussed in the Introduction, results on the potential genotoxicity of nicotine at relevant concentrations are conflicting and thus are not inconsistent with the relative absence of animal studies demonstrating nicotine as a complete carcinogen.

## Conclusion

Overall, the animal studies on nicotine carcinogenicity available to date do not suggest that nicotine is a complete carcinogen. However, there has been no single study that would have passed the current criteria of a

well-designed study according to generally agreed-upon guidelines, e.g., in terms of number and range of dose levels, statistical power, or biomonitoring of nicotine exposure by its metabolites in body fluids. Therefore, conclusive studies are missing. Nevertheless, two negative (lack of carcinogenic effect) studies were the highest adequacy scoring studies in this group. In conclusion, limited evidence suggests an association between long-term nicotine exposure and a lack of a complete carcinogenic effect.

## Potential of nicotine to modulate carcinogenesis

This section reviews studies in which nicotine administration was tested for a potential modulating (stimulating or lack of stimulating) effect of tumorigenic processes induced by chemical and physical treatments and genetic manipulations (Section "Cancer induction by physical, chemical, and transgenic means") as well as cellular treatments (xenograft studies, Section "Cancer xenograft studies"). At the end of each of these two sections, both high and low-adequacy score studies are discussed in aggregate and a conclusion is provided for each respective part of the review. Subsequently, in an attempt to further stratify results

To facilitate comparisons, the (sub )studies were grouped into high and low adequacy scoring studies with overall scores subjectively set to  $>2$  and  $\leq 2$ , respectively.

\*As judged by the authors of the respective studies, where "positive" indicates stimulating carcinogenesis and "negative" indicates a lack of carcinogenic effect.

†Number of different laboratories contributing studies.

by study design variables, the results of these two sections are further discussed regarding the impact of various study design parameters used, e.g., route of administration, dose and dose rate, or the impact of immune competence.

### Cancer induction by physical, chemical and transgenic means

A summary of reported conclusions from all reviewed studies in this category is given in Table 5. A description of high-adequacy studies is provided in the section below. A narrative description of low-adequacy studies as well as a more detailed overview of all studies evaluated in this category is provided in the Supplementary material (Supplementary Tables 4 and 2).

**Oral administration.** In a relatively early study, Freedlander et al. (1956) investigated the potential of nicotine to modulate the tumorigenicity of UV light in mice ( $n=100$ ), which, under the conditions of the study, developed ear and eye tumors. The nicotine dose administered via the drinking water was increased from approximately 3 to 18 mg/(kg  $\times$  d) over the course of the 7-month study. Tumor incidences were 42% in the control group and 35% in the group treated with nicotine via the drinking water. Thus, the authors concluded that there is no additive or co-carcinogenic effect of nicotine with UV light. There was no group exposed to nicotine alone.

In a study by Liu et al. (2011), the bladder of Wistar rats was infused with *N*-methyl-nitrosurea (MNU) sufficient to induce bladder cancer within a few months. After the end of the MNU treatment, rats were randomized into four groups treated intragastrically with nicotine doses from 0 to 11 mg/(kg  $\times$  d) for 2 months ( $n=12$ ). Although the groups were very small, animals were necropsized at given time points up to the conclusion of the study at 4 months. The authors reported a nicotine dose-dependent increase in tumor size (no data shown). In the high-dose nicotine group, two metastases were found. In addition, a nicotine dose-dependent increase in the frequency of mutated *p53* genes was reported, which was apparently determined by immunohistochemistry. The authors concluded that nicotine may play an important role in the development of bladder cancer.

Murphy et al. (2011) investigated the modulating activity of nicotine on NNK-induced carcinogenesis. Female A/J mice ( $n=18$ ) were initiated with a single i.p. injection of 80 mg/kg NNK and exposed to nicotine hydrogen tartrate via the drinking water for up to 11 months. In order to be able to study the potential impact of nicotine on various stages of the NNK-induced tumorigenesis, nicotine was administered either for 0.5 months before NNK administration, for 11 months after NNK administration, or throughout the study (with NNK administration after 0.5 months of nicotine exposure). Water consumption was lower than in sham-exposed mice, leading to an approximate nicotine dose of 6 mg/(kg  $\times$  d). Plasma nicotine and cotinine levels were determined throughout the study and found to be relatively low, 0.66 and 31 ng/ml respectively, compared with levels reported for users of nicotine delivery products (Table 1). Lung tumor multiplicity was approximately 20, and there was no effect of nicotine on multiplicity, size and progression from benign to malignant lung tumors regardless of the nicotine exposure regimen. The advantages of this study were the targeted nicotine exposure at various stages of tumorigenesis, the chronic duration and the biomonitoring of nicotine exposure. Limitations were the intermediate group sizes relative to other studies in this category and the relatively low nicotine exposure as assessed by biomonitoring.

Maier et al. (2011) conducted a relatively similar study to that above but with the use of AB6F1 mice. The nicotine dose delivered via the drinking water was estimated at 10 mg/(kg  $\times$  d). No nicotine-related toxicity was observed. Nicotine exposure was for 3 months after i.p. treatment with 100 mg/kg NNK for three weeks ( $n=10$ ). A control group exposed to nicotine alone was included in this study. Although a relatively high NNK

dose was used, the average tumor multiplicity was only approximately 1.5, which may be related to the relatively short duration and the loss of pulmonary tumor susceptibility by crossing of susceptible A/J with less susceptible C57Bl6 mice. Nicotine did not enhance lung carcinogenicity in terms of tumor multiplicity and volume. There was a numerical trend to a higher incidence of lung tumors in the nicotine-treated groups, which was not statistically significant. Serum cotinine levels were at 137 ng/ml, which according to the authors' suggestion would be comparable with an NRT user with exposure to a 22 mg nicotine patch.

Maier et al. (2011) also used a mouse model transgenic for a mutated human *Kras* gene, which is known to progress rapidly through pulmonary tumorigenesis, i.e., *Kras*<sup>LA2</sup>. In this model, tumors are apparent as early as 2 weeks of age, and they progress to adenocarcinomas within several months. Two weeks of nicotine exposure starting at an age of 3 weeks did not change tumor multiplicity or tumor burden. Six weeks of nicotine exposure starting at an age of 6 weeks did not affect tumor multiplicity, size or burden. A daily nicotine dose of 10 mg/(kg × d) was estimated ( $n = 5$ ). If this treatment was continued until the death of the mice (approximately for 5 months), nicotine did not alter the overall life span either. It is unclear whether the life span was limited by the lung tumors, because data on tumor multiplicity or size were not reported for this latter sub-study. In the lung tumors found in this study, nicotine did not alter the activation status of a number of proteins associated with cellular growth signals, such as Akt, Erk, or the proliferation marker Ki-67. The group sizes in this sub-study are among the smallest in this category.

Hermann et al. (2014) studied the effect of nicotine administration on pancreatic cancer development in various mouse models, apparently exposed to nicotine at a nominal concentration of 20 mg/(kg × d) via the drinking water. *Kras*<sup>+/LSLG12V<sub>geo</sub></sup>; *Elas-tTA/tetO-Cre* and *Kras*<sup>+/LSLG12D</sup>; *Trp53+/LSLR172H*; *Pdx-1-Cre* (KPC) mice were exposed for 18 and 20 months, respectively, which resulted in a 10- and 4-fold increase in the area of pancreatic intraepithelial neoplasia lesions, respectively ( $n = 7$ ). In addition, the grade or severity of the lesions was higher in the nicotine-treated groups. For the KPC mouse, an increased number of circulating pancreatic cells was also observed that was considered indicative of a metastatic phenotype. For the *Kras*<sup>+/LSLG12V<sub>geo</sub></sup> mouse, a urinary cotinine level of 210 ng/ml was reported, which the authors suggested was similar to the level of intermediate smokers. This suggestion, however, was based on a reference that only reported blood cotinine levels, and in their abstract, the authors

indeed discussed their result on the basis of blood levels. The reported value, as a urinary cotinine level, is much lower than what has been reported for users of nicotine delivery products (Table 1 and Figure 2). A plethora of mechanistic investigations was included in this study pointing to a nicotine-induced acinar cell dedifferentiation via down-regulation of *Gata6*. For instance, nicotine seemed to increase tumor growth from murine acinar cells in nude mice, if these cells harbored a mutated *Kras* gene and were deficient of *Gata6* ( $n = 2-3$ ).

Nishikawa et al. (1992) investigated the potential of nicotine to modulate the pancreatic carcinogenesis initiated by *N*-nitrosobis(2-oxopropyl)amine in female Syrian Golden hamsters. After completion of the initiation, nicotine was administered for 9 months at an estimated dose of 2.5 mg/(kg × d) via the drinking water ( $n = 30$ ). The pancreas was carefully examined in serial sections of four anatomical lobes. In addition, the spleen and the duodenum were grossly examined. The authors claimed to find a tendency to enhanced pancreatic carcinogenesis in terms of adenocarcinoma and dysplasia incidence; however, no statistically significant effects for nicotine were reported.

**Low-adequacy score studies.** Relevant studies with low-adequacy scores using oral administration (Freedlander & French 1956; Ito et al. 1984; Nakada et al. 2012), cheek pouch application (Chen & Squier 1990; Chen et al. 1994), dermal application (Bock & Tso 1976; Bock 1980), s.c. injection (Rana & Bhagat 1970; Bhagat & Rana 1971; Gurkalo & Volfson 1982; Habs & Schmähl 1984; Schuller et al. 1995; Bersch et al. 2009; Hayashi et al. 2014) and i.p. injection (Habs & Schmähl 1976; Davis et al. 2009; Iskandar et al. 2013) were identified and evaluated. A study on the potential of nicotine to modulate chemotherapy was conducted using osmotic minipumps to administer nicotine (Berger & Zeller 1988), presumably via the s.c. route, although the actual route of administration was not specified. These studies are described in the Supplementary material as a narrative (Supplementary Table 4) and as an entry in the evidence table in the Supplementary material (Supplementary Table 2). No inhalation studies were identified.

### Discussion of aggregate evidence.

**High-adequacy score studies.** All high-adequacy score studies used oral nicotine administrations. Of the eight high-adequacy (sub-)studies identified and evaluated for a potential role of nicotine in modulating the carcinogenic effects of inducing treatments, four were negative

(lack of a stimulating effect) and four were positive (stimulating effect). The positive rat study by Liu et al. (2011) used an intragastric and thus most probably bolus administration of nicotine. The study is difficult to interpret because actual tumor data were not provided by the authors. Other studies in this category used sustained nicotine administration to mice or hamsters via the drinking water. The second set of two positive sub-studies in this context investigated the effect of nicotine administration on pancreatic neoplastic developments in particular models of *Kras* mutant mice (Hermann et al. 2014). However, in another *Kras* mutant mouse model, no effect of nicotine on pulmonary carcinogenesis was observed (Maier et al. 2011). Nominal nicotine doses of 10 (racemic mixture) and 20 mg/(kg × d) (unknown type of nicotine) were estimated for the negative and positive *Kras* mutant studies, respectively. With the uncertainty in the type of nicotine used in the positive study, a potential dose–response difference between the two studies as a reason for the differential outcome remains a possibility. A difference in the *Kras* biology of both models might also explain the difference in outcomes. Both studies, however, employed very small group sizes. Importantly, various sub-studies from two laboratories did not find a stimulating activity of oral nicotine for lung tumors induced by NNK, a tobacco-derived *N*-nitrosamine, regardless of the temporal relationship between the administrations of the two compounds (Maier et al. 2011; Murphy et al. 2011).

**Low-adequacy score studies.** Twenty-seven low-adequacy scoring (sub-)studies were identified and evaluated in this category. The three oral studies were all negative; included here are two studies with A/J mice that are susceptible to lung tumor formation (Freedlander & French 1956; Nakada et al. 2012). Combination with either urethane or NNK did not increase tumor risk. However, cheek pouch application studies with hamsters were reported to be positive in combination with chemical carcinogens (Chen & Squier 1990; Chen et al. 1994). Rather complex nicotine responses were obtained in studies that tried to identify whether nicotine would play a role in a rather common model for tobacco carcinogenesis, i.e., mouse skin painting (Bock & Tso 1976; Bock 1980). The main author concluded that the results of his experiments showed that nicotine *per se* can enhance carcinogenesis induced by the combination of benzo[*a*]pyrene and a promoter, although the mechanism of this presumed co-carcinogenesis and its relevance to humans remained unclear. Of the s.c. injection studies, a stimulating effect of nicotine was reported for pancreatic, pulmonary and

gastric cancer models upon induction with dimethylbenzanthracene (Bersch et al. 2009), hyperoxia (Schuller et al. 1995) and methylnitronitrosoguanidine (Gurkalo & Volfson 1982), respectively. Other studies with s.c. nicotine injection were negative or apparently even showed a protective effect, e.g., in a colitis-associated cancer model (Hayashi et al. 2014). Upon i.p. injection, nicotine was reported to stimulate NNK-induced carcinogenesis in A/J mice (Davis et al. 2009; Iskandar et al. 2013), which apparently is in contrast to the results of NNK studies with A/J mice and nicotine administration via the drinking water (see “High-adequacy score studies” section). It would be interesting to understand from a mechanistic point of view, why bolus administrations of nicotine, as few as thrice per week, can result in a positive modulating effect.

**Summary of the evidence.** Across the many different routes of administration, which includes both sustained and bolus administrations, study results on carcinogenicity were not consistent, providing about half positive and half negative results, regardless of the adequacy score obtained. Except for the skin painting studies with mixed results, those studies with the highest statistical power in terms of group sizes tended to be negative. Most studies had very small group sizes. Dose–response studies were not performed. Dose–response analyses across studies were difficult due to the often missing description of the actual nicotine type used and the difficulty of assessing dose or dose rate with bolus injection studies administering only a few injections per week. However, a trend to a dose–responsive behavior across studies cannot be excluded. Dose-responsiveness would certainly need to be assessed in future studies using the biologically active nicotine enantiomer. Biological plausibility is difficult to assess, as the high-adequacy score studies lack sufficient mechanistic investigations. Of particular interest is to develop a better understanding of the toxicodynamic similarities and differences between sustained and bolus administrations. This is especially important in light of the well-known effect of nicotine dosing regimens on the induction and desensitization of nAChRs (Marks et al. 1985; Renda & Nashmi 2014; Lam et al. 2016). Interestingly, none of the studies in this section was conducted with immunocompromized animals, in contrast to the majority of studies conducted with xenografts (see “Cancer xenograft studies” section).

**Conclusion.** Conflicting results were reported for the effect of nicotine in cancer models with physical, chemical, or transgenic initiation. Additional

**Table 6.** Reported findings of relevant studies for evaluating the potential cancer modulating activity of nicotine in xenograft studies.

Note: To facilitate comparisons, the (sub )studies were grouped into high and low adequacy scoring studies with overall scores subjectively set to >2 and ≤2, respectively.  
\*As judged by the authors of the respective studies, where “positive” indicates stimulating carcinogenesis and “negative” indicates a lack of carcinogenic effect.  
†Number of different laboratories contributing studies.

mechanistic insight is required to allow an understanding of the negative and positive findings reported. Thus for animal studies using chemical, physical or transgenic models to initiate cancer, there is inadequate evidence for an association between nicotine exposure and the presence of or lack of a stimulating effect on carcinogenesis.

**Cancer xenograft studies**

In general, studies in this category investigated the ability of nicotine exposure to modulate (stimulate) tumor growth after cancer cells were inoculated in animals. Immunocompromized mice were commonly used in these studies. A summary of reported conclusions from all reviewed studies in this category is given in Table 6. A description of high-adequacy studies is provided in the section below. A description of low-adequacy studies as well as a more detailed overview of all studies evaluated in this category is provided in the Supplementary material (Supplementary Tables 4 and 2, respectively).

**Oral administration.** Jarzynka et al. (2006) were interested in the combined effect of estradiol and nicotine on the growth of A549 cells subcutaneously (s.c.) implanted into nude ovariectomized mice. Nicotine was administered at two estimated doses of 20 and 40 mg/(kg × d) via the drinking water for 36 d (n = 8). Estradiol was administered via a pellet co-injected with the A549 cells. There is no mentioning of a sham operation with a pellet containing no estradiol as a

control for potential physical effects. Nicotine by itself resulted in a numerical but statistically non-significant increase in tumor growth in the high dose group, which was characterized by the authors as positive (stimulates tumor growth). At the lower dose of nicotine, no effect was observed (data not shown). There was a statistically significant increase in cell proliferation due to nicotine in the tumor tissue, while there was only a numerical increase in vascularization. Estradiol by itself also resulted in a numerical but statistically non-significant increase in tumor growth. The combined administration of both substances resulted in an increased tumor volume that was significantly higher than in the untreated control or in the high-dose nicotine group. Given the moderate, if any, effect of nicotine on tumor growth in this study, the claimed combination effect could have been an estradiol effect and with no particular contribution by nicotine.

Shin et al. (2004) investigated the role of nicotine in athymic nude mice inoculated with a gastric cancer cell line into the gastric wall. Nicotine was administered for 3 months at two doses of 11 and 62 mg/(kg × d) via the drinking water (n = 10). A decreased body weight effect was observed at the high nicotine dose. The area of the gastric wall covered by a tumor increased with increasing nicotine doses from 18 mm<sup>2</sup> to 25 mm<sup>2</sup> to 30 mm<sup>2</sup> in parallel to an increasing cell proliferation index. Neovascularization determined as microvessel density as well as the expression of the vascular endothelial growth factor (VEGF) in the tumor tissue also increased in a parallel manner. These effects were dependent on the activity of cyclooxygenase-2 (COX-2). The authors concluded that their study revealed “a direct promoting action of nicotine on the growth of gastric tumor.”

Wong et al. (2007) inoculated colon cancer cells s.c. into the flank of nude BALB/c mice. Nicotine was administered for 25 d at two doses of 10 and 40 mg/(kg × d) via the drinking water (unknown group size). No effects on drinking water consumption and body weight development were observed. No group size was reported. Higher tumor volumes were observed in a dose-dependent manner, and the tumor growth was attenuated by β<sub>1</sub>- and β<sub>2</sub>-adrenoceptor antagonists given by i.p. injections thrice per week for the course of the study. Plasma adrenaline and cotinine levels increased with increasing nicotine doses; the authors did not comment on the surprising finding of low levels of cotinine in the sham-treated group. In the tumor tissue, increased levels of both types of adrenoceptors, COX-2, prostaglandin E<sub>2</sub> (PGE<sub>2</sub>), VEGF and microvessel density were observed. The authors concluded that the nicotine-dependent effect on tumor growth would be mediated by β-adrenergic activation and angiogenesis. The same

group investigated an s.c. xenograft model with colon cancer cells that were pretreated *in vitro* with 10 nM, 100 nM and 1000 nM of nicotine for 5 h before inoculation (Ye et al. 2004). After 3 weeks, the volume of the tumors was increased in a nicotine concentration-dependent manner. The formation of these tumors could be inhibited by incubation of the cancer cells with inhibitors of the epidermal growth factor receptor or inhibitors of 5-lipoxygenase prior to treatment with nicotine.

Maier et al. (2011) inoculated AB6F1 mice with three different cell lines derived from NNK-induced lung adenocarcinoma of the same strain and observed tumor development. The F1 generation of A/J and C57Bl6 mice, i.e., AB6F1 mice, was used in order to combine the A/J susceptibility to developing lung cancer and the C57Bl6 apparent preference for consuming nicotine-containing drinking water. Within the 2 weeks of nicotine exposure at an estimated dose of 10 mg/(kg × d), no modulating effect on tumor growth or the development of metastases was found. The group sizes in this sub-study are among the smallest in this category ( $n = 5$ ).

Li et al. (2015) investigated the potential antagonist effect of nicotine on the chemotherapeutic effect of the epidermal growth factor receptor (EGFR) inhibitor erlotinib. In one sub-study, nicotine was administered via the drinking water for 20 d after s.c. inoculation of PC9 NSCLC cells in nude BALB/c mice (group size unknown). A nicotine dose of 20 mg/(kg × d) was estimated, which resulted in serum cotinine levels of approximately 37 ng/ml. The authors did not explain why their control mice also had cotinine levels of up to 20 ng/ml. A small but statistically significant increase in tumor volume was observed. Interestingly, a parallel group of mice was exposed to i.v. nicotine injections for 5 d/week at doses of 0.06 mg/kg, and, in this group, a similar increase in tumor growth was observed as with the oral nicotine administration. Between days 21 and 36, erlotinib was also administered and inhibited the further growth of the xenograft tumors. Growth inhibition was less effective in the group with prior and concomitant oral nicotine exposure compared to that with i.v. injections. Nevertheless, in comparison with a control without nicotine, both types of nicotine treatment attenuated the growth-inhibitory effect of erlotinib.

**Subcutaneous administration.** Pratesi et al. (1996) administered nicotine s.c. via osmotic minipumps to athymic nude BALB/c mice that were s.c. inoculated with tumor fragments developed from a small cell lung cancer cell line in the same mouse strain. Nicotine doses of 0.8

and 8 mg/(kg × d) were maintained for 2 weeks either shortly after inoculation or after tumors had grown to a certain size ( $n = 5-10$ ). The time until a target tumor size was obtained was used to measure the potential modulating activity of nicotine on tumorigenesis. No effect was observed for nicotine, while in a parallel experiment a modulating activity for serotonin was claimed. The study suffered from very small group sizes.

Hao et al. (2013) investigated the effect of nicotine on pulmonary metastasis formation from murine melanoma cells given i.v. to immunocompromized RAG2<sup>-/-</sup> mice. Nicotine was administered via s.c. osmotic minipumps at a dose rate of 13 mg/(kg × d), resulting in nicotine plasma levels of approximately 49 ng/ml ( $n = 10-13$ ). Within 2 weeks, nicotine doubled the tumor volume determined via luminescence labeling of the melanoma cells. The nicotinic growth effect on metastases was largely diminished in RAG2<sup>-/-</sup> β2-nAChR<sup>-/-</sup> mice generating by crossing the RAG2<sup>-/-</sup> with mice knocked-out for this nAChR receptor. The authors interpreted these results to demonstrate that nicotine would exert an immunoinhibitory effect on TK cells via β2-nAChR, which would otherwise contain the growth of these melanoma metastases.

Berger and Zeller (1988) investigated a potential interference with the chemotherapy of two types of rat cancer models. In a leukemia model driven by inoculation of rat leukemia cells and treated with cyclophosphamide for chemotherapy, nicotine had a borderline significant enhancing effect on the development of leukemia, i.e., nicotine was interpreted to impair the chemotherapy by cyclophosphamide, although only at the lowest of three cyclophosphamide doses. Nicotine was administered for 2 weeks via an osmotic minipump (no specification of the route of administration but presumably s.c.,  $n = 8$ ) at doses of 2.5 and 5 mg/(kg × d). No effect on the development of leukemia in this xenograft model was seen by nicotine alone.

**Low-adequacy score studies.** This section includes relevant studies with low-adequacy scores using i.v. injection (Paleari et al. 2008; Li et al. 2015), oral administration (Heesch et al. 2001; Natori et al. 2003; Al-Wadei et al. 2009; Lee et al. 2010; Al-Wadei et al. 2012; Nakada et al. 2012; Banerjee et al. 2013; Khalil et al. 2013; Banerjee et al. 2014; Liu et al. 2015), dermal application (Davis et al. 2009), s.c. injection (Warren et al. 2012) and i.p. injection (Davis et al. 2009; Maier et al. 2011; Molino et al. 2011; Treviño et al. 2012; Pillai et al. 2015; Yuge et al. 2015). In one study, nicotine was administered via an osmotic minipump; however, the actual route of delivery was not specified (Improgo et al. 2013). These studies are described in the Supplementary material as a narrative

(Supplementary Table 4) and as an entry in the evidence table in the Supplementary material (Supplementary Table 2). No inhalation study was identified.

### *Discussion of aggregate evidence.*

**High-adequacy score studies.** Of the high-adequacy score (sub-)studies with oral nicotine administration, the four studies conducted with immunocompromized mice were considered positive by their authors (Shin et al. 2004; Jarzynka et al. 2006; Wong et al. 2007; Li et al. 2015), while the three sub-studies conducted with immunocompetent mice were negative (Maier et al. 2011). This differentiation is not as clear-cut as it might first seem, because the estimated nicotine dose used in the negative sub-studies were also among the lowest in this category. It is unclear whether other differences in study design could be responsible for the difference in outcome between these studies. The genetic set-up and thus the aggressiveness of the cancer cells used might also affect the responsiveness to nicotine.

**Low-adequacy score studies.** Twenty-four xenograft (sub-)studies with low-adequacy scores were identified. For those studies with oral nicotine administration, all were considered positive by their authors with the exception of those with intentionally low nicotine doses that were not expected to be positive and used for mechanistic investigations (Banerjee et al. 2013, 2014). Also, the negative study using s.c. nicotine administration was not intended to dose nicotine high enough to enhance tumor growth but rather to see whether lower doses might interfere with radio- and chemotherapy (Warren et al. 2012). The two studies with nicotine administration via s.c. minipumps used two different types of immunocompromized mice; the one with the higher estimated nicotine dose was positive (Hao et al. 2013), while the one with the lower estimated nicotine dose was negative (Pratesi et al. 1996). The sub-studies with i.p. nicotine injection were all positive except for two sub-studies, for which the nicotine administration frequency was not clearly identified (Maier et al. 2011). For the bolus types of nicotine administration, daily doses or dose rates are difficult to estimate and compare with other types of administrations. Both studies with sustained or bolus administration were considered positive, i.e., stimulating tumor growth from inoculated cancer cells. An interesting finding was the similar increase in tumor growth seen in one study after either oral or i.v. nicotine administration (Li et al. 2015). In contrast, in another study nicotine administration via both drinking water and i.p. injections were negative (Maier et al. 2011). In this category, studies using both

immunocompetent (Heeschen et al. 2001; Natori et al. 2003; Davis et al. 2009; Nakada et al. 2012) and immunocompromized mice (Paleari et al. 2008; Al-Wadei et al. 2009; Lee et al. 2010; Al-Wadei et al. 2012; Treviño et al. 2012; Improgo et al. 2013; Khalil et al. 2013; Li et al. 2015; Liu et al. 2015; Pillai et al. 2015; Yuge et al. 2015) were considered positive by their authors. The negative studies by Maier et al. (2011) and Molfino et al. (2011) as well as the positive study by Davis et al. (2009) used immunocompetent animals.

**Summary of the evidence.** There was a certain degree of consistency for the finding of cancer growth stimulating effects of nicotine across types of cancer cells used, sites of inoculation, routes of nicotine administration and laboratories conducting the studies in finding positive effects of nicotine in xenograft models. Such effects may also be biologically plausible in view of the *in vitro* findings on cell proliferation, anti-apoptosis, cell migration and invasion, and angiogenesis (see "Introduction" section), although a critical assessment of the degree of coherence in translating the *in vitro* findings to *in vivo* effects seem to be missing. The strengths of association between nicotine exposure and xenograft growth were variable from modest effects to severe differences as compared to controls. However, most studies used very small group sizes and dose-response analyses were rarely conducted.

**Conclusion.** The majority of studies in this category were positive across various routes of administration, various cancer cell types for inoculation, various organs and various types of hosts. In particular, positive findings were observed after both sustained and bolus nicotine administration. Some of the negative study results may be explained by the relatively low doses administered. Thus, a majority of studies provides sufficient evidence for an association between nicotine exposure and enhanced carcinogenesis of cancer cells inoculated in mice.

### *Discussion of cancer-modulating activity studies*

Of the approximately 70 studies or sub-studies covered in this category, about 60% demonstrated the stimulation of a carcinogenic effect and about 40% showed a lack of such effect (Tables 5 and 6). To assess the relevance of these experimental animal studies to users of nicotine delivery systems (e.g., NRT products and ENDS), it would be helpful to understand the differences in study design parameters that may be responsible for the conflicting findings.

**General insufficiency of available information.** Common obstacles for the current assessment are the frequent absence of information on the type of nicotine (base, salt, and enantiomer) used in these studies as well as the common lack of information on nicotine exposure (e.g., accurate assessment of plasma nicotine or cotinine levels). Furthermore, practically all published studies did not provide sufficient information to fully judge their findings' relevance and significance in a comparative manner. For instance, very few studies report body weight changes following nicotine treatment. At high doses, nicotine exposure in animals has been shown to result in a significant reduction in growth rate (body weight increase or maximally attained body weight), presumably due to a decrease in food intake (Wilson & DeEds 1936). Such an effect may or may not affect tumor growth in many of these relatively short-term studies. Such information would be useful for evaluating the actual nicotine exposure levels as well as the relevance of a carcinogenic effect (or lack of).

Most studies suffered from very small group sizes. Most studies in this category were conducted with mice, and consequently, no species-specific pattern for an effect or lack of an effect could be determined. The studies were conducted in three dozen different laboratories, and occasionally conflicting findings were derived in the same laboratory depending on the study conditions.

**Segregation of studies by type of tumor initiation.** Another approach to interpret the studies reviewed in this section is by the process in which the carcinogenic effect was established. Thirty-five studies or sub-studies used exposure of chemical or physical carcinogens or transgenic mice in combination with nicotine (Table 5) while 35 studies or sub-studies, most of which were mouse studies, used the inoculation of cancer cells or tumor fragments (Table 6). Of the first group, 16/35 studies (46%) were positive, while the others were negative or, in few cases, even showed a protective effect. Of the second group, 24/35 were positive (69%). Among the three sub-studies that used mice transgenic with mutant *Kras*, two from one laboratory were positive (Hermann et al. 2014) and one was negative (Maier et al. 2011). In the study by Nakada et al. (2012), sequential dosing with NNK and nicotine was negative, while nicotine administration after inoculation with cancer cells was positive. For studies investigating the cooperative effect of NNK and nicotine, most but not all were negative. Overall, nicotine's effect on chemical/physical/transgenic-induced carcinogenesis does not appear to be dependent on the type of

initiating agent. For xenograft studies, the evidence appears to be sufficient for a stimulating effect of nicotine on the growth of inoculated cancer cells.

**Segregation of studies by route of administration.** Both positive and negative results were found in studies investigating virtually all routes of nicotine administration. For determining study adequacy criteria, those routes of administration that a user of nicotine delivery systems may be exposed to, were weighed higher than others. This is justified based on the relevance for extrapolating the respective data to humans. However, the findings from animal studies evaluated in this section do not indicate that the influence of nicotine on carcinogenesis is dependent on a particular route of nicotine administration.

**Comparative evaluation by dose or dose rate.** Both a modulating effect and a lack of an effect on carcinogenesis were observed upon sustained nicotine administration or bolus nicotine administration. It is interesting to note that a similar increase in tumor growth was reported in a study using i.v. (bolus) or oral (sustained) nicotine administration side by side (Li et al. 2015). Of the studies using bolus administration of nicotine, there is no separation of positive and negative studies by dose stratification. Also, there is no stratification observed for the modulation of either physical/chemical- or cancer cell-induced carcinogenesis. If average daily doses are calculated for the positive bolus studies, these average doses are much lower than those that can be achieved by sustained exposure to nicotine, such as via drinking water, presumably due to rapid nicotine turnover. It remains to be investigated whether and how transient high nicotine exposures obtained by bolus administration might be sufficient to trigger events that may eventually stimulate carcinogenesis. Because of the rapid nicotine metabolism in the animal species investigated, it can be assumed that upon bolus administration, all nicotine is metabolized between administrations, even if performed on a daily basis. It may be concluded that the trigger obtained by a bolus administration seems to survive long enough to maintain a certain level of stimulating activity, such as proliferative or anti-apoptotic, between dosing intervals. This phenomenon may also be related to the observation that cancer cells were triggered to faster tumor growth upon inoculation by prior *in vitro* incubation with nicotine (Ye et al. 2004; Yu et al. 2012; Yu & Chang 2013). Otherwise, a repeated transient trigger, even with intermediate phases without nicotine present, may also be sufficient. A third and even more hypothetical possibility would be that the effects would not be

**Figure 4.** Cancer modulating activity as judged positive or negative by respective authors for mouse studies using nicotine administration via drinking water (stratified by average estimated daily nicotine dose). Positive modulating activity refers to stimulating carcinogenesis. Negative activity is the lack of a stimulating effect. Symbols characterize chemical/physical/transgene-based (circles) and cancer cell-based (triangles) studies with high (full symbols) and low (open symbols) adequacy scores.

mediated by nicotine itself but rather by its metabolites which have longer half-lives.

Of the drinking water studies in mice, as the largest example of sustained nicotine dosing, about half of the (sub-)studies were considered positive by their authors (cf. Figure 4). Most studies using chemical/physical carcinogens or transgenes in combination with nicotine were negative, while the majority of those using cancer cells to initiate the carcinogenic effect were positive. The negative sub-studies with inoculated cancer cells had relatively low estimated daily doses of nicotine administered. In particular, in the study by Jarzynka et al. (2006), the low dose at 20 mg/(kg × d) was negative, while the high dose at 40 mg/(kg × d) was claimed positive by the authors (on the basis of only 20% increase in tumor volume). Among the drinking water studies, several used measures of tumor volume to assess the effect of nicotine. An attempt to establish a relationship across studies between the daily doses of nicotine received from the drinking water and tumor volume failed. Without demonstrating a dose–response relationship, the presence of a possible threshold for nicotine’s modulating effect could not be established. Interestingly, with chemical cancer induction, only comparatively low nicotine doses were used, which may or may not explain the negative results in this category. All these interpretations for possible trends in the available data or the lack thereof should be viewed cautiously due to the uncertainties in reporting the form of nicotine used. Future studies with chemical, transgene and cellular induction of cancer should aim at establishing nicotine dose–response relationships and potentially determine a nicotine threshold, if any, for these modulating effects.

Mixed results were also observed with other sustained exposure methods. For example, using s.c. administration via osmotic minipumps at a dose of 8 mg/(kg × d), no stimulating effect on tumor growth was found in a study with mice (Pratesi et al. 1996). In contrast, a dermal patch delivering a nicotine dose of 25 mg/(kg × d) resulted in a 1.7-fold increase in tumor volume in mice (Davis et al. 2009).

**Nicotine biomonitoring.** If it is difficult to judge studies by their nominally reported doses, it may be more useful to stratify them by biomonitoring data that reflect tissue levels of nicotine or its metabolites. Systemic concentrations of nicotine and cotinine at a given per-kg dose are lower in mice than those in users of nicotine delivery systems (Figure 2) due to the rapid metabolism of both the parent compound and the primary metabolite. This rapid metabolism may not be reflected by their concentrations in urine, as these would integrate across the metabolic rate differences between species. The usefulness of all biomonitoring data depends on the knowledge of sampling periods relative to nicotine administration. However, sampling information is not available for the few studies that actually provided biomonitoring data.

Biomonitoring data are only available for seven recent studies, several of them conducted in sub-studies (Figure 3). In the negative drinking water study performed using mice by Murphy and colleagues, plasma nicotine and cotinine levels were far below those found in users of nicotine delivery systems (Table 1), while urinary levels were similar (Murphy et al. 2011). In another drinking water study using a murine model, which administered a slightly higher estimated daily nicotine dose than in the previous study, a blood cotinine value similar to the average cotinine levels in users of nicotine delivery systems was reported (Maier et al. 2011). In this latter study, no modulation by nicotine of the carcinogenicity induced by NNK, transgenic mutant *Kras*, or inoculation with NNK-transformed cells was observed. A positive (stimulates tumor growth) study by Wong et al. (2007) reported plasma cotinine values of 43 and 169 ng/ml after nicotine administration via the drinking water at estimated doses of 10 and 40 mg/(kg × d). The urinary cotinine levels in the positive (stimulates tumor growth) drinking water study by Hermann et al. (2014) with mutant *Kras* mice were far below those of users of nicotine delivery systems (see “Oral administration” section).

Thus, based on the biomonitoring data available, a real stratification for negative and positive studies is still not possible. Biomonitoring data are critical for evaluating studies on the potential carcinogenesis of nicotine.

Hopefully, future investigations will collect such data with consideration of species-specific toxicokinetics and transparent sampling methodology.

**Applicability of the two-stage model of carcinogenesis.** For the nicotine studies conducted in combination with chemical carcinogens, it might be informative to determine the amount of information available related to investigating the classic two-stage cancer model with initiation and promotion or investigating a co-carcinogenic effect (Moolgavkar & Knudson 1981; Cohen & Ellwein 1991). In fact, several published studies were indeed designed to unravel such relationships. Both cancer models (two-stage and co-carcinogenic) require specific timing for the dosing schedule of compounds under investigation. To facilitate the interpretation of data on this topic, the information whether any chemical compound given in combination with nicotine was given concomitantly (c) or sequentially (s) is available in the Supplementary material (Supplementary Table 2).

Murphy et al. (2011) explicitly tested this question using nicotine administration in various combinations with NNK: nicotine was either given before, after or both before and after NNK administration. In all three cases, nicotine had no effect on NNK-induced tumorigenesis. In other studies, when nicotine was given after NNK, contrasting effects were observed: In two studies with nicotine administration via the drinking water, nicotine did not enhance tumorigenesis when NNK was given i.p. at 80–100 mg/kg either once or thrice (Maier et al. 2011; Nakada et al. 2012). In another study when NNK was i.p. injected twice at 100 mg/kg, an enhancing effect by nicotine was reported upon i.p. nicotine administration (Iskandar et al. 2013). Perhaps a critical difference between the studies is the nicotine dose rate.

Habs and Schmähl (1984) investigated whether nicotine would affect tumor initiation or promotion by MNU by either administering nicotine during the week before MNU injection or for 3 months after MNU injection. Neither approach of nicotine treatment affected tumor incidence, size or histology.

Nicotine was also used in two studies with chemically-induced bladder cancer (Ito et al. 1984; Liu et al. 2011). The study by Liu and colleagues was considered positive after intragastric administration of nicotine, the other by Ito et al. was negative after administering nicotine via the food at a lower dose.

Skin painting studies have been the classic model to test for two-stage carcinogenesis and co-carcinogenesis (Rubin 2001; in particular for cigarette smoke, cf., Rubin 2002). In view of this, Bock et al. conducted a series of studies to determine the role of nicotine in tobacco

condensate-related dermal carcinogenesis (Bock & Tso 1976; Bock 1980). Bock concluded that the results of his “experiments show that the enhancement of BaP-TPA carcinogenesis by nicotine is not due to a specific effect of the alkaloid on either initiation or promotion.” However these studies left him uncertain whether nicotine could be a co-carcinogen (Bock 1980).

It is obvious that insufficient information is available to classify nicotine in the context of the classic two-stage carcinogenesis model. This is not possible until we have a better understanding as to why some studies report tumorigenesis-stimulating effects from nicotine exposure while others report no effect. Cohen and Ellwein (1991) suggested that the difficulty with this terminology (e.g., two-stage carcinogenesis model) is that it relies on specific experimental protocols for its definition. For instance, one feature of a promoter in the initiation-promotion model is reversibility, which has not been investigated for nicotine.

**Impact of immune competence.** Several immunocompromized mouse models were used in the evaluated studies, including nude, severe combined immunodeficient (scid) and non-obese diabetic (NOD)-scid mice. The development of immunodeficient mouse models (athymic nude mice) in the 1960s for *in vivo* investigation of human tumor growth and metastasis continued in the 1980s with the development of the scid mouse (RAG<sup>+/−</sup> or <sup>−/−</sup>) and into the 1990s with the NOD-scid mouse (Shultz et al. 2014). The adaptive immune system in these mouse models is severely compromised, but the innate immune system remains intact to varying degrees depending on the model (Shultz et al. 2014). Recent studies have demonstrated that the innate immune system, especially natural killer (NK) cells, plays a critical role in suppressing tumor growth in nude mice (Guerriero et al. 2011; Klier et al. 2011; Zhou et al. 2011).

Numerous published studies have clearly demonstrated that nicotine administration can inhibit both the innate and adaptive immune systems (Kalra et al. 2004; Han et al. 2014). In fact, nicotine administered for 6 weeks (s.c., minipump) to immunocompromized mice (RAG<sup>−/−</sup>) inhibited NK cell function and accelerated B16 tumor cell burden and metastasis in these animals (Hao et al. 2013). When dosed with sufficiently high nicotine doses using various routes of administration, 18 of 19 (sub-)studies with immunocompromized mice evaluated in this review were considered positive by the studies' authors. It would be interesting to learn if these positive modulating effects of nicotine on tumor growth were dependent on immunosuppression (combination of animal model- and nicotine-derived).

Overall conclusion

There are numerous positive studies regarding the modulating activity of nicotine for the growth of inoculated cancer cells (1) using various kinds of cancer cells administered to various sites, (2) in various strains of mice, (3) employing various routes of nicotine administration and (4) conducted in various laboratories. Several of these studies investigated biological plausibility and suggest that angiogenesis might be involved as one mode of action by which nicotine may exert this growth-stimulating effect on cancer cells. Overall, there seems to be sufficient evidence to conclude that nicotine can stimulate carcinogenesis of inoculated cancer cells in laboratory animals, especially in immunocompromized mouse models.

The studies involving co-exposure with chemical carcinogens cannot be conclusively interpreted as showing either the presence or absence of a modulating effect of nicotine on the carcinogenesis of these compounds because of conflicting results and major qualitative or quantitative limitations. Thus, the existing evidence is inadequate to support the presence or absence of a carcinogenesis-modulating effect of nicotine when combined with chemical co-exposures.

For a risk assessment of nicotine, it would be helpful to understand why in some animal models, nicotine was indeed positive (stimulates carcinogenesis) while in others, negative (lack of stimulation). The current assessment did not produce any stratifying study design variable (e.g., dose) or biological principle that would allow a separation between positive and negative study outcomes with regard to a cancer-modulating effect of nicotine.

Studies with nicotine metabolites

Nicotine has a very short half-life in the laboratory rodent species commonly used for pharmacological and toxicological studies with nicotine (Matta et al. 2007) (cf., "Comparative toxicokinetics" section). Metabolites, such as cotinine and 3'-trans-hydroxycotinine, have a longer half-life than nicotine, though still shorter in rodents than in humans. In studies with mixed results with nicotine itself, e.g., some odd dose-response behavior in mouse skin painting studies (Bock 1980), it seemed possible that nicotine metabolites could either participate or interfere with the potential of nicotine to act as a carcinogen itself or to modulate the carcinogenesis of other materials. Several relevant studies were identified on these topics, and a summary of reported conclusions from all reviewed studies in this category is given in Tables 7 and 8. A more detailed description of high-

adequacy score studies is provided in the section below. A description of low-adequacy score studies as well as a more detailed overview of each study evaluated in this category is provided in the Supplementary material (Supplementary Tables 4 and 3, respectively). At the end of the current section, both high and low-adequacy score studies are discussed in aggregate, and a conclusion on this part of the review is provided.

Oral administration

Truhaut et al. (1964) exposed Wistar rats to cotinine via the drinking water at an estimated dose of 63 mg/(kg × d) (n ≥ 60 for cotinine group; n ≥ 15 for control).

The rats showed signs of toxicity mainly during the first 6 months of the study. Between months 8 and 18, 12/15 rats that died in the cotinine group had malignant tumors, mainly lymphosarcomas in the digestive tract. Such lymphosarcomas were not observed in any of the 15 control rats euthanized after 18 months. Of the 45 rats euthanized after 18 months of cotinine exposure, several had benign lesions.

LaVoie et al. (1985) wondered whether nicotine metabolites might be involved in smoking-related bladder cancer and, therefore, exposed Fischer 344 rats to urinary nicotine metabolites, i.e., cotinine, *trans*-NNO, and the mixture of *cis*- and *trans*-NNO, at toxic doses via the drinking water ( $n \geq 33$ ). No carcinogenic effect was seen after 18 months of exposure. To explore the potential promoting activity of the exposure to nicotine metabolites, parallel groups were initiated by dietary treatment with *N*-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide (FANFT), a model carcinogen for the induction of bladder cancer in rats. In addition to bladder cancer, tumors at other sites also were induced by FANFT. The nicotine metabolites did not promote the FANFT-induced bladder cancer, rather if anything, NNO inhibited this effect. However, NNO induced an increase in forestomach cancer.

Freedlander et al. (1956), in a relatively early study, investigated the potential of NNO to modulate the tumorigenicity of UV light in mice ( $n = 100$ ), which under the conditions of this study developed ear and eye tumors. The NNO dose administered via the drinking water was increased from approximately 12–56 mg/(kg  $\times$  d) over the course of the 7-month study. Tumor incidences were 42% in the control group and 41% in the group treated with NNO via the drinking water. The authors concluded that there is no additive or co-carcinogenic effect of NNO and nicotine (see above) with UV light. No treatment group was exposed to NNO alone.

Nakada et al. (2012) applied two animal tumor models used for investigating the modulating potential of nicotine in parallel to cotinine (unclear group sizes). In one of these models, A/J mice were exposed to an initiating dose of NNK (80 mg/kg, i.p.), which was followed by cotinine administration via the drinking water. Two concentrations of cotinine were offered (with saccharine) resulting in estimated doses of 20 and 60 mg/(kg  $\times$  d). After 4 months, adenocarcinomas had not yet developed, while the incidence of adenomas was significantly increased in the high cotinine dose group compared to the NNK-only group. The low dose of cotinine, as well as the same low dose of nicotine, did not lead to a significant effect on adenoma multiplicity.

## Dermal application

Bock (1980) investigated, in two sub-studies ( $n \geq 45$ ), whether the co-carcinogenic effect that he had seen with nicotine in mouse dermal carcinogenesis studies might be related to nicotine metabolites, which might have explained some of the odd dose/time–response behaviors observed with nicotine. Cotinine and NNO, respectively, were mixed with BaP and 12-O-tetradecanoylphorbol-13-acetate (TPA) in an experimental setup that showed co-carcinogenic activity with nicotine. With cotinine, there was a statistically significant increase in cancer incidence for the high dose tested. This increase was, however, not considered to be sufficiently high to suggest that metabolic formation of cotinine could account for the co-carcinogenic effect of nicotine in this assay system. With NNO, there was a statistically significant decrease in cancer incidence at both doses tested.

## Low-adequacy score studies

This section includes relevant studies with low-adequacy scores using oral administration (Freedlander & French 1956; Schmähl & Osswald 1968; Nakada et al. 2012). Additionally, in view of the contrasting results seen in rats, Boyland (1968) exposed mice to cotinine using various routes of administration. However, little information is available, as the data were only presented in a preliminary manner. Thus, this series of sub-studies was given a very low-adequacy score (for a detailed description, see Supplementary material, Supplementary Table 4). Boyland (1968) concluded that cotinine might induce bladder cancer after implantation into the bladder within a pellet, but would be negative after dermal, s.c., and subscapular injections. Relevant concurrent controls were missing in these studies, which are necessary when using the bladder pellet implantation technique, which is known to induce bladder cancer by itself (Clayson 1974).

## Discussion of aggregate evidence

**High-adequacy score studies.** In those studies investigating the effect of cotinine as a potential complete carcinogen, a positive effect observed with cotinine in the earliest study (Truhaut et al. 1964) could not be reproduced in a second study with the same strain of rats and the same concentration of cotinine in their drinking water (Schmähl & Osswald 1968). The authors of the second study even claimed to have administered a higher overall cumulative dose of cotinine, which is difficult to judge. The most recent study on this topic

(LaVoie et al. 1985), with a higher adequacy score than the other studies in this section, did not reveal any increase in carcinogenicity by either cotinine or NNO.

Interestingly, the mouse skin painting study (Bock 1980) also suggested a trend towards higher tumor modulating activity of cotinine and a clear inhibition by NNO, as observed in the rat study in combination with FANFT (bladder carcinogen). The strongest positive cotinine study was in combination with NNK (Nakada et al. 2012). Mechanistically, the same anti-apoptotic effects were implicated in this study for cotinine that were also suggested for nicotine.

**Low-adequacy score studies.** The two oral low-adequacy score studies on cotinine in rats (Schmähl & Osswald 1968) and NNO in combination with urethane in mice (Freedlander & French 1956) were both negative. However, cotinine seemed to stimulate tumor growth in mice inoculated with Lewis carcinoma cells (Nakada et al. 2012). A complex study in mice using various routes of administration (Boyland 1968) was difficult to evaluate due to the lack of information.

### Summary of the evidence

Studies with two nicotine metabolites were found, both testing their potential complete carcinogenicity or their potential to modulate carcinogenesis. The results from studies with cotinine were inconsistent, as were the study designs used therein. Biological plausibility, such as nAChR activation by cotinine was not assessed in the positive studies. There seemed to be a dose–response effect in one study, although only two dose levels were tested. For NNO, all available studies point to negative, if not protective effects, across various models. No biological plausibility was offered for this finding. It might be interesting to investigate the interaction of NNO with nAChRs.

### Conclusion

Definitive carcinogenicity studies according to current standards are not available. The overall evidence is inadequate regarding a potential carcinogenic activity of cotinine, while there seems to be limited evidence for a lack of carcinogenicity of NNO.

### Limitations of the current review

The current review has comprehensively and critically evaluated available evidence from epidemiological and animal carcinogenesis experiments. The review did not discuss the plethora of mechanistic information that is

available on the potential of nicotine (and its metabolites), e.g., for epigenetic effects and in particular for modulating signal transduction pathways involved in various aspects of carcinogenesis, such as cell proliferation, inhibition of apoptosis, angiogenesis and invasion (Jensen et al. 2012; Russo et al. 2012; Chu et al. 2013; Improgo et al. 2013; Grando 2014; Niu & Lu 2014; Schaal & Chellappan 2014; Schuller 2014). There is also considerable published data on the interaction of nicotine and related compounds with nAChRs and its potential impact on carcinogenicity, but this information is not discussed in this review.

A surprisingly large number of animal studies were identified in this review with many different species, doses, routes and rates of administration, and co-exposures. Given the limited information provided on the dosing (e.g., the form of nicotine used in dosing) and the fast metabolism of nicotine in these species, it is extremely difficult to compare studies based on actual tissue levels of nicotine or its metabolites. Comparisons between studies are further complicated by the fact that biomonitoring was only rarely performed and methodological information was often missing.

The potential for nicotine to modulate the carcinogenic process induced by other materials may be relevant for humans in cases when carcinogenic processes are already present. However, all the studies reviewed that combine chemical carcinogens with nicotine exposure were conducted at very high doses of the initiating carcinogen, which may trigger other mechanisms of carcinogenesis not found at lower and more relevant doses. In addition, the cancer cells routinely used in xenograft models induced a very rapid and aggressive growth of tumors. It remains to be established to what degree such studies are relevant for human carcinogenesis and should serve as the basis for evaluating a modulating role of nicotine.

The potential of nicotine and its metabolites for endogenous nitrosation to yield carcinogenic *N'*-nitrosamines was not specifically addressed in this review. However, any potential risk stemming from such nitrosation should have been observed in the nicotine studies reviewed.

### Knowledge gaps

Additional information on the long-term effect of nicotine exposure in humans is needed to determine the potential carcinogenic risk. This could be obtained in human studies by extending NRT use for longer periods than currently approved. Such studies should be conducted in former smokers as these users are presumably the most vulnerable population due to possible

presence of already induced (pre-) cancerous processes. A second approach would be to follow up on studies with users of ENDS, again in former smokers and in ENDS users who had never smoked tobacco products.

Definitive laboratory animal studies are needed to assess the complete carcinogenic potential of nicotine. The design of an appropriate study or set of studies is challenging. For example, there are various routes of nicotine exposure for humans [inhalation (buccal/nasal), oral, dermal]. Doses and concentrations of nicotine and its metabolites in users of nicotine delivery systems need to be considered when designing and interpreting a carcinogenicity study of nicotine. Different allometric and biomonitoring parameters should be selected for a species comparison, of which systemic blood levels (with understood circadian changes) should be monitored.

For a better assessment of the modulating activity of nicotine, dose–response relationships would need to be established considering the same study design parameters as discussed above. Very recently, a nicotine threshold effect was considered possible based on *in vitro* and *in vivo* studies (Schuller 2014). Because the suggested mechanisms for this modulating effect are mainly non-genotoxic, a threshold of exposure to induce such effects may exist and requires further characterization for its potential application to users of nicotine delivery systems considering both toxico-kinetic and –dynamic species differences.

Nicotine exposure in an immunocompromized mouse model (nude, athymic) resulted in a positive modulating effect of carcinogenesis (tumor xenografts) in over 90% of the studies. This observation deserves further investigation, in light of nicotine’s ability to suppress the innate and adaptive immune response. It would be interesting to learn if there is an association between nicotine’s immunosuppressant activity and the observed cancer modulating effect in immunodeficient mice. This

hypothesis could certainly serve as an alternate explanation for understanding the consistent cancer modulating effects of nicotine observed in this model system.

Overall conclusions

What are the potential carcinogenic effects of nicotine *per se* at levels found in users of nicotine delivery products? At present, public health statements on the subject indicate that “nicotine is not generally considered to be a carcinogen” (International Agency for Research on Cancer 2012). The latest report from the US Surgeon General concluded that “the evidence is inadequate to infer the presence or absence of a causal relationship between exposure to nicotine and risk for cancer” (US Department of Health and Human Services 2014). The purpose of the present review is to evaluate the strength of published scientific evidence, in both human and animal studies, for nicotine *per se* to act as a complete carcinogen or as a modulator of carcinogenesis. The findings from this comprehensive evaluation are summarized in Table 9.

For human studies, there appears to be inadequate evidence for an association between nicotine exposure and the presence of or lack of a carcinogenic effect. A limited number of studies are available on the subject with only one epidemiological study identified that investigated the cancer risk from using NRTs. The study provided no evidence for an effect of NRT use on cancers of the lung, the gastrointestinal tract, or overall. However, inadequate evidence was concluded due to the limited follow up time (12 years) for a chronic disease such as cancer and due to the low dose of nicotine (NRT) routinely used by participants of this study.

In animal studies, suggestive but still limited evidence suggests an association between long-term nicotine exposure and a *lack* of a complete carcinogenic effect.

Table 9. Strength of evidence classification for nicotine to act as a carcinogen or carcinogenesis modulator in human and animal studies.

\*Sufficient evidence: conclusive or highly suggestive studies are available between nicotine exposure and either a lack of carcinogenic effect or a carcinogenic effect.  
†Limited evidence: the evidence from available studies is indicative of an association between nicotine exposure and either a lack of carcinogenic effect or a carcinogenic effect. Conclusive studies are missing.  
‡Inadequate evidence: there is only conflicting or incomplete evidence available.

The two rodent studies with the highest adequacy scores reported the absence of a carcinogenic effect with lifetime exposure to nicotine (Toth 1982; Waldum et al. 1996). However, conclusive studies using current bioassay guidelines are missing.

In approximately 70 animal studies, nicotine was investigated for its ability to modulate (stimulate) the carcinogenic process induced by administration of chemical/physical carcinogens, inoculation with cancer cells, or in transgenic models. In 35 studies using chemical/physical carcinogens and transgenic models, there appears to be inadequate evidence for an association between nicotine exposure and the presence of or lack of a modulating (stimulate) effect on carcinogenesis. Evidence was deemed inadequate due to the large number of conflicting studies (approximately 50%). In contrast, a majority of studies (69%) provide sufficient evidence to conclude that nicotine can stimulate carcinogenesis of inoculated cancer cells in animals, especially in immunocompromized mouse models. Inconsistent findings on nicotine's ability to modulate carcinogenesis may result from the use of numerous animal models and a wide variety of dosing regimens for nicotine administration. Comparisons between studies, however, are complicated by the fact that nicotine biomonitoring was rarely performed and methodological information was often missing.

Overall, taking both the human and animal studies into consideration, there appears to be inadequate evidence to conclude that nicotine *per se* does or does not cause or modulate carcinogenesis in humans. This conclusion agrees with the recent US Surgeon General's 2014 report on the health consequences of nicotine exposure (US Department of Health and Human Services 2014).

## Acknowledgements

The authors acknowledge the editorial assistance of Eileen Y. Ivasauskas of Accuwrit Inc. and the assistance of Alan I. Goldsmith of the Research Information Group, Altria Client Services LLC (ALCS), who performed the literature search in Medline and Embase databases. The authors thank Mohamadi Sarkar and Scott Appleton of ALCS for their scientific review of this paper. The authors also gratefully acknowledge the valuable comments offered by the editor and those offered by four external reviewers selected by the Editor and anonymous to the authors. These comments were very helpful in revising the manuscript.

## Declaration of interest

The employment affiliation of the authors is shown on the cover page. M. W. F. is a current employee of ALCS and H. J. H. is a former employee of Philip Morris International. H. J. H. served as a paid consultant to ALCS for preparation of this

review. H. J. H. is an independent toxicology consultant for commercial firms including companies that manufacture and sell tobacco products. ALCS is an affiliate of Philip Morris USA Inc., U.S. Smokeless Tobacco Company LLC and NuMark LLC which are manufacturers and marketers of various tobacco products in the United States including cigarettes, smokeless tobacco and e-vapor products, respectively. The authors have not testified in litigation or represented ALCS or affiliates in meetings with FDA regarding the topic of this review. The ALCS legal department reviewed this paper solely in connection with intellectual property protection. The opinions and conclusions of the authors are their own, and do not necessarily reflect the position of ALCS or its affiliates.

# Obsolete tobacco control themes can be hazardous to public health: the need for updating views on absolute product risks and harm reduction

Lynn T. Kozłowski<sup>1\*</sup> and David B. Abrams<sup>2,3,4</sup>

## Abstract

**Background:** Leading themes have guided tobacco control efforts, and these themes have changed over the decades. When questions arose about health risks of tobacco, they focused on two key themes: 1) how bad is the problem (i.e., absolute risk) and 2) what can be done to reduce the risk without cessation (i.e., prospects for harm reduction). Using the United States since 1964 as an example, we outline the leading themes that have arisen in response to these two questions. Initially, there was the recognition that “cigarettes are hazardous to health” and an acceptance of safer alternative tobacco products (cigars, pipes, light/lower tar cigarettes). In the 1980s there was the creation of the seminal theme that “Cigarettes are lethal when used as intended and kill more people than heroin, cocaine, alcohol, AIDS, fires, homicide, suicide, and automobile crashes combined.” By around 2000, support for a less dangerous light/lower tar cigarette was gone, and harm reduction claims were avoided for products like cigars and even for smokeless tobacco which were summarized as “unsafe” or “not a safe alternative to cigarettes.”

**Discussion:** The Surgeon General in 2014 concluded that by far the greatest danger to public health was from cigarettes and other combusted products. At the same time the evidence base for smokeless tobacco and alternative nicotine delivery systems (ANDS) had grown. Product innovation and tobacco/nicotine bio behavioral, epidemiological and public health sciences demonstrate that low nitrosamine smokeless tobacco (e.g., Swedish snus), and ANDS have substantially lower harms than cigarettes. Going forward, it is important to sharpen themes and key messages of tobacco control, while continuing to emphasize the extreme lethality of the inhaled smoke from cigarettes or from use of any combusting tobacco product.

**Summary:** Implications of updating the leading themes for regulation, policymaking and advocacy in tobacco control are proposed as an important next step. A new reframing can align action plans to more powerfully and rapidly achieve population level benefit and minimize harm to eliminate in our lifetime the use of the most deadly combustible tobacco products and thus prevent the premature deaths of 1 billion people projected to occur worldwide by 2100.

## Background

### Leading themes

For much of the 20<sup>th</sup> Century, cigarette smoking was for many a socially acceptable, even fashionable activity with considerable social pressure on some individuals to become smokers [1, 2]. By the end of that century, cigarette smoking had been recognized as a major cause of premature death and disability, [3] and health authorities from around the world had mobilized to stop the public health tragedy of tobacco use [4]. When questions arose about the ill-effects of a very popular product like tobacco, they usually focused on two key themes: 1) how bad is the problem (i.e., the absolute risk) and 2) what can be done to reduce the risk without giving up such products (i.e., the prospects for harm reduction [5]). Using the United States (U.S.) as an example, we outline the leading themes that have arisen in response to these two questions. Both the issues of absolute risk and harm reduction have continuously been present, but perspectives have changed significantly. This is not a review of epidemiological results, but a consideration of these leading themes, which provide a view of changing emphases in tobacco control.

Although the history of societal responses to tobacco use is centuries old, [1] the 1964 publication of “Smoking and Health: Report of the Advisory Committee to the Surgeon General on Smoking and Health” [6] marks a starting point for concerted tobacco control efforts in the U.S.. At every point since 1964, tobacco control has had a dominant view of both absolute risk and tobacco harm reduction. Table 1 provides an overview and summarizes some of the variations in views on these two themes.

### “Cigarettes are hazardous to your health,” but you have options

The 1964 Surgeon-General’s Report had considerable impact on media reports, organized action, and on the American public [7]. It can be underappreciated that at the time, the report raised concerns about a major, then respected industry. There were earnest hopes that the risks of cigarettes could be reduced, and lower-risk options were noted. For example, the conclusions for lung cancer read:

Cigarette smoking is causally related to lung cancer in men; the magnitude of the effect of cigarette smoking far outweighs all other factors. The data for women, though less extensive, point in the same direction....

The risk of developing cancer of the lung for the combined group of pipe smokers, cigar smokers, and pipe and cigar smokers, is greater than for non-smokers, but much less than for cigarette smokers. The data are insufficient to warrant a conclusion for each group individually (Chapter 9, p. 196).” [p.37]

In addition to efforts to prevent and treat cigarette smoking, there was advice from the Surgeon General, the President of the American Medical Association, and the Consumers Union that switching from cigarettes to cigars or pipes was a useful option for those who would not quit tobacco completely, and the sales of cigars boomed [8]. Lung cancer expert Ernst Wynder at the Sloan-Kettering Cancer Institute reported in *Life Magazine* that the technology that had put a man on the moon could be used to make safer cigarettes [9]. Days before the 1964 Surgeon-General’s Report was released

**Table 1** Timetable of leading tobacco control themes in the United States on absolute risk and harm reduction options

Approximate dates in United States	Leading Absolute Risk Theme	Harm Reduction
1964	Cigarettes are hazardous to men and likely to be for women.	Cigars and pipes are safer than cigarettes; lower tar cigarettes may be safer; the science that put a man on the moon will develop a safer cigarette soon.
1980	Cigarettes are lethal when used as intended and kill more people than heroin, cocaine, alcohol, AIDS, fires, homicide, suicide, and automobile accidents combined.	Cigars and pipes are safer than cigarettes; Light/lower tar cigarettes may be safer; Snus is less harmful (in Sweden/Scandinavia).
1987	Cigarettes are lethal (as above) and cause lung cancer, heart disease, emphysema; smokeless tobacco and cigars are not safer alternatives to cigarettes.	Avoidance of indication of harm reduction from cigars and smokeless tobacco; tar and nicotine testing stopped, but “low tar” and “Light” claims still marketed and misleading.
2001	All cigarettes are equally lethal; all tobacco products are unsafe.	No recognition/encouragement of less harmful tobacco use.
2014	“The burden of death and disease from tobacco use in the United States is overwhelmingly caused by cigarettes and other combusted tobacco products...”  All cigarettes are equally lethal; all tobacco products are unsafe.	An acknowledgement of the special deadliness of the smoke from combustion, primarily from smoking cigarettes and the potential for harm reduction.
2015 [Herein Proposed]	Cigarettes and other smoked products are the most deadly; non combusted tobacco and alternate nicotine delivery products, including medical replacement therapies are unsafe, but relatively low in risk. Smoke for the nicotine but die from the tar.	An acknowledgement of the special deadliness of smoking and development of ways to increase harm reduction in continuing users of lethal tobacco products by displacing smoking with much less harmful tobacco or nicotine.

the first very-low-tar yield (so called, “light”) ventilated-filter cigarette was released—with tar and nicotine yields printed on the pack [9]. The sales of filtered, light/lower-tar cigarettes boomed, and the government started testing cigarettes for tar and nicotine yields in 1967; a lower-tar race was underway [9]. In Senate testimony in 2007, the Federal Trade Commissioner reported that in 1967, “most public health officials believed that reducing the amount of ‘tar’ in a cigarette could reduce a smoker’s risk of lung cancer; therefore, it was thought that giving consumers uniform and standardized information about the tar and nicotine yields of cigarettes would help smokers make informed decisions about the cigarettes they smoked [10].” The National Cancer Institute, in collaboration with the cigarette industry, actually undertook research to help develop less-hazardous cigarettes [11].

In retrospect, the aggressive, optimistic acceptance of cigarette harm reduction was a tragedy. The disaster of the light/low-tar cigarette was compounded by the product’s popularity and the fact that risks were not meaningfully reduced though the perception was that they had been reduced [12]. It would take decades of research to prove that lower-tar cigarettes were not worthwhile reduced-harm products [13] and to understand that inhaled cigar and pipe smoke (inhalation was more likely in former cigarette smokers) were significantly dangerous to health [14]. The recognition was yet to come that it was the toxic inhaled smoke from the combusting of tobacco (the mode of delivery) that carried the greatest harm (cigarettes, cigars, pipe and roll your own and hookah).

The history of cigarette warning labels in the U.S. has been described in detail [15]. In 1966, cigarette packages only (not advertising) were required to have the warning: “Caution: Cigarette Smoking May Be Hazardous to Your Health.” This is a warning that lives in infamy as a tragically cautionary stance. In 1970, cigarette advertising was banned on television and radio, and the package warning was strengthened to: “Warning: The Surgeon General Has Determined That Cigarette Smoking Is Dangerous to Your Health.” By 1985, warnings included indication that cigarettes caused lung cancer, heart disease, and emphysema. In 1973, the ban on broadcast advertising was extended to little cigars [15].

#### **Cigarette control in the 1980s: the extraordinary dangers of smoking**

In the 1980s, “cigarette control” forces were learning new ways to battle the powerful public relations/marketing symbols that the industry employed in defense of their products. Broader advertising bans on cigarettes were being proposed in the U.S. [16] and elsewhere [17–19]. The industry argued that a ban for cigarettes would

be a “slippery slope” or the “thin edge of the wedge,” and that other, popular unsafe products (alcohol, cars, salt, butter, and fat) would be next in line for advertising bans and other meddlesome regulatory constraints. A group of international “cigarette control” experts from 35 countries were convened in 1985 by the American Cancer Society, and as a result, Michael Pertschuk led the development of an influential advocacy guide [20]. This “smoking control media handbook” reproduced the industry’s arguments and gave birth to symbolically powerful responses that reframed the issues.

The degree of regulation appropriate for alcohol and alcohol advertising is a debatable point which is resolved by each society as it sees fit, balancing both the serious social and health hazards of alcohol, the ability of most users to maintain moderate, safe levels of consumption, and evidence that the moderate use of alcohol is not a health threat for many people.

Automobiles involve serious risk, but they are indispensable to modern society, and the risks are substantially reduced when cars are engineered safely and appropriate traffic laws are enacted, enforced and obeyed.

Fat, sugar, and salt are essential to life and become hazardous only when consumed in excess.

**Cigarettes are the only legal product that, when used as intended, are lethal.** [Emphasis added.]

**Smoking is not only a hazard to the smoker, but also to the nonsmoker who is involuntarily exposed to the smoke. Consuming fat, sugar, and salt is not a hazard to bystanders.** [Emphasis added.]

**Smoking kills more people than heroin, cocaine, alcohol, AIDS, fires, homicide, suicide and automobile accidents COMBINED.** [Emphasis added.]

Cigarette control experts used some variant of this three-pronged argument to reframe their strategy: 1) “cigarettes are the only legal products that are deadly when used as intended by the manufacturer,” 2) involuntary smoking is a unique concern, and 3) the deadliness of cigarettes is extreme (i.e., defective) and much greater than for other products [21].

The force of these arguments was critical to the “de-normalization” of cigarettes and to the institution of cigarette control measures (increased taxation, clean indoor air laws) that have contributed to the decrease in cigarette prevalence. The phrasing “harmful when used as intended by the manufacturer” has a long history in product liability law and government regulations. (To appreciate why this principle got nowhere in relation to legal tobacco liability issues, see these accounts [22, 23]).

The *Smoke Signals* handbook helped popularize the framing of these arguments for cigarettes being different from other popular, harmful products (like alcohol).

This theme helped distance cigarette control advocates from those who wanted to restrict marketing for other unsafe products which, although not without some risk to individual users, were much less dangerous than cigarettes on a population-wide basis. In the U.S., society and regulators have accepted quite open marketing for a number of sometimes popular, unsafe products (e.g., alcohol, acetaminophen, prescription medications) [24]. At the time, the cigarette control field understood that claiming a product was unsafe was the beginning of an argument, not the end of the argument, on how a product should be marketed.

Consistent with the unintended consequences of the unfortunate theme reported in *Life Magazine* that the technology that had put a man on the moon could be used to make safer cigarettes [9] and the subsequent misguided entrusting of the industry to work with government to develop safer cigarettes, the greatest fraudulent claims of the light/low tar cigarette era was born. The 1980s still represented a boom time for light/lower-tar cigarettes. These ventilated-filter products made up the large majority of cigarette sold, and they were mistakenly perceived as less dangerous than higher tar cigarettes by many consumers aided by Government testing and labeling where the unscrupulous industry found ways to cheat the Federal Trade Commission (FTC) testing method until testing was stopped [25, 26].

#### **'Cigarette control' becomes 'tobacco control' in 1980s: Smoking is bad and there are no product options to consider**

In 1987, rotating warnings were finally added to packages and advertising of smokeless: "WARNING: This product may cause mouth cancer," "WARNING: This product may cause gum disease and tooth loss," and "WARNING: This product is not a safe alternative to cigarettes." Despite the substantive contrast between the warnings (and the evidence base) for cigarettes and smokeless tobacco, public health messages in the 1980 and 1990s often stressed that smokeless tobacco was not safer than cigarettes. This theme essentially blurred the distinction between combustion and non-combustion in ironic contrast to the encouragement to switch to pipe and cigars made by experts in 1964 [8]. For example, the Surgeon-General's Report for Kids, when asking "If smokeless tobacco was 'safer' than cigarettes," answered "NO WAY!", even though their elaboration of that point (and the official warning) made clear that the health problems were really quite different from those known for cigarettes. See discussion of this in [27, 28]. Perhaps as a strong backlash to the fraudulent behavior of an

untrustworthy industry (i.e. the light/low tar debacle) the pendulum understandably swung to the other extreme. The data that not all tobacco products were equally harmful (i.e., smoked versus smokeless) was overshadowed by the truism that there was some harm caused by all tobacco use. Thus the harm reduction baby was thrown out with the bathwater and a major swing to an all or nothing stance was adopted. A justified rage and mistrust of the industry led to a emergent prohibitionist theme. One exception was arising in the Scandinavian countries especially Sweden in the late 1970's with the introduction in Sweden of a moist form of Swedish snus and a voluntary standard (Gothiatek) to produce and market a low nitrosamine form of smokeless tobacco. However, this recognition of harm reduction was ignored and met with suspicion and hostility by the rest of the world (see more detailed discussion below).

It is important to distinguish between products that are "not safe" and those that are "not safer" than cigarettes. Special efforts were made to discourage smokeless tobacco as a safer alternative to cigarettes, and one should assume that, if the claim "Not Safer than cigarettes" was scientifically defensible, it would have been made in the official warnings. This distance between not safe and deadly can be large, and it is a very limited contribution to health communication to say a product is "not safe" with no indication of the level of absolute or relative risk of harm [28].

"Cigarette control" was subsumed by "tobacco control," and such an incorporation contributed to a blurring or conflation of issues across classes of products that are in fact quite different from cigarettes in the damages caused. Given the dangers of consumer products (e.g., alcohol, a number of prescription and non-prescription pharmaceuticals, automobiles, processed meats), one should be reluctant to use the argument on the extreme deadliness of cigarettes to oppose the use of other products that, while not safe, will likely be or have been shown to be substantially less dangerous than cigarettes. Understanding the complex systems forces at work that have blurred the cigarette/combustible tobacco focus as the prime cause of preventable death is a challenge. The basic cigarette/combustible class of product has been "improved" (in appeal, addiction liability and toxins) but is largely unaltered and has dominated sales for over 120 years, a period aptly termed the "Cigarette Century" and more recently the "Golden Holocaust." [2, 29]. By 1987 the FTC stopped doing machine-smoked tar and nicotine tests [10]. By 2001, the hope for a reduced-risk combusted cigarette seemed officially gone [13]. We turn now to a discussion of the dramatically changing landscape and the need to further sharpen the important themes going forward in tobacco control.

## Discussion

### Understanding and managing differential risks of alternative nicotine delivery products (ANDS), non-combusted tobacco products, and combusted tobacco products

Since 1964, major themes missed a core principle: The substantially greatest harm is from the toxic smoke of combusted, inhaled tobacco. In a 2014 summary of 50 years of research on tobacco and health, the U.S. Surgeon General finally concluded, “The burden of death and disease from tobacco use in the U.S. is overwhelmingly caused by cigarettes and other combusted tobacco products....” [30]. This opened the door to an evidence-based re-depolymorphism of harm reduction in tobacco control, but there have been challenges to getting the field to step through that door. Some of the challenge arises, we think, because of a mistaken but understandable lumping of all tobacco/nicotine products into the same bin of being highly lethal when used as intended and more dangerous than an array of other unsafe products and activities. Tobacco control needs to be guided by a modern understanding of differential risks from different modes of delivery of tobacco/nicotine containing products in the practice of tobacco control, not crude, unjustified claims of product risks based on the fraudulent industry behavior of the light/low tar disaster.

The tobacco and nicotine delivery marketplace has changed dramatically with three landmark developments: (a) introduction and acceptance of alternative forms of medicinal nicotine replacement therapies (NRT's) for smoking cessation deemed safe for over-the-counter sales and for long-term use if need be; (b) the recent introduction and promise of future improved innovation of the disruptive technologies of a range of alternative nicotine delivery systems (ANDS) such as disposable, tank and Mod vapor products (e-cigarettes); and (c) rigorous and convincing longitudinal epidemiological data from Sweden/Scandinavia of the successful use of low nitrosamine Swedish snus for harm reduction.

Tobacco control is at a critical crossroads. Issues of absolute risks and harm reduction options have become divisive in the science, practice and policy [31, 32] arenas as the marketplace changes and as old status quo arguments are questioned. The rhetoric and argumentation arising from smoking (i.e. combustible products: primarily cigarettes, cigars, pipes, roll your own and hookah) and health does not translate well to the substantially less harmful classes of products: smokeless tobaccos and various emerging electronic cigarette innovations for nicotine aerosol inhalation (vape), or other ANDS, that, like NRT's, de-couple nicotine delivery from the complex lethal toxins of tobacco combustion.

The 2014 Surgeon-General's report [30] encourages a new framework in tobacco/nicotine control. The dominant argument against *a product that was lethal when used as intended and more deadly than a list of dangerous products* applies to cigarettes in particular and the toxic inhaled smoke from combustible tobacco products. It is frankly unlikely that this argument fits at all for vaping (aerosol delivery of nicotine in a humectant, without the carbon monoxide, over 4,000 chemicals and the extreme levels of harm from the over 60 known human carcinogens in deadly smoke) or smokeless tobacco, especially the low nitrosamine forms produced in Swedish type snus. The toxicological and epidemiological evidence pertaining to harms from these products is very different than for combustibles [33–35]. There are many reasons for discouraging the use of several popular consumer products, especially when it comes to preventing youth initiation of any and all forms of nicotine delivery systems (NRT or ANDS) or tobacco products, regardless of their differential harm profiles. However, it is now crystal clear that it is the inhaled deadly smoke from cigarettes/combustibles that stands alone by orders of magnitude as a pinnacle of deadliness that greatly exceeds the disease and disability costs of a large number of consumer products added together as well as NRT, ANDS and all forms of non-combusted tobacco [36, 37].

A view that treats all tobacco/nicotine use as equally bad is no longer consistent with the evidence base and represents a runaway rhetoric. Given the relative risks of different classes of tobacco/ANDS products, one should not let a broad commitment to “tobacco control” distract from the most important goal of cigarette/combustible smoking elimination. Those who have come to treat all tobacco/nicotine products as equally repugnant would have an expected resistance to any loosening of the dominant themes and frameworks appropriate to the prior 50 years of the tobacco product and control landscape. Given the disruptive technological innovations of the last 5 years, one can expect a new period of uncertainty and strong emotion as old foundational assumptions, fears and justifiable tobacco industry mistrust is stirred up.

Nonetheless, the new reality of ANDS, smokeless/snus and NRT's must be fully recognized and thus, there is an urgent critical need for old views to be re-examined, some retained, others set aside (some prior tried and true past views may now in fact be counterproductive or destructive) and new frameworks developed to fit the new emerging scientific evidence and the evolving and rapidly transforming landscape of alternative nicotine modes of delivery in the marketplace [31, 32, 38–40]. We see the current turmoil as an understandable loosening of prior views, and the chaos is inevitable as it portends a new synthesis or systems integration—described

so aptly by Kuhn in the history of scientific revolutions from Ptolemy to Copernicus to Einstein [41]. The 120+ year dominance of the “cigarette century” ushered in with the disruptive technology of the cigarette rolling machine in 1882 is being seriously challenged, perhaps for the first time in 140 years, by the emergence of newer and much less harmful modes of nicotine delivery, and is explored in detail elsewhere: [42] First by the introduction of medicinal nicotine therapy, [32] second by evidence of low harm smokeless tobacco in Sweden/Scandinavia, [43] and third by emergence of disruptive technological innovations in aerosolized nicotine delivery (e.g. vaping of e-cigarettes) without any tobacco per se [31, 32, 42].

**Is snus or ANDS more lethal than any of these separately: heroin or cocaine or alcohol or AIDS or fires or homicide or suicide or automobile crashes?**

The credible arguments for the risks of snus or vaping products do not range to the level of highly lethal, but are ranging more at the lower levels of “not safe” (see Fig. 1). The established disease epidemiology for smokeless tobacco products as used in Scandinavia or the U.S. demonstrates that these products are substantially less dangerous than cigarettes [33, 44]. A review of the epidemiological literature on snus concluded, “While smoking substantially increases the risk of cancer and CID [circulatory ischemic disease], any increase from snus use is undemonstrated, and if it exists is probably about 1 % of that from smoking,” [45] and was updated with little change in conclusions [34]. Although ANDS are yet to be regulated to assure consistency and quality control, the more

carefully done studies and estimates for the risk from vaping ANDS are also low [35, 46]. While ANDS are not harmless, it seems like hyperbole to argue that ANDS would ever approach the lethality of cigarettes when either is used as intended. Would one argue that there would be more premature deaths from exclusive snus or ANDS use than from alcohol? The CDC estimates the annual deaths from alcohol at about 88,000, [47] compared to all-cause mortality of over 520,000 for cigarettes [37]. Is there an estimate for premature deaths from snus or ANDS use that would come close to being the number of deaths from alcohol? We are unaware of any.

Despite significant epidemiological studies that could provide direct comparative data on all-cause mortality from smokeless tobacco use and cigarette use, [48, 49] it is striking how hard it is to find this direct comparison within the same dataset. In their discussion, the authors of these major reports acknowledge that the risks of smokeless tobacco are “considerably smaller than the risks associated with cigarette smoking,” but express their disagreement that smokeless tobacco be marketed as a less-harmful alternative to smoking; and intentionally they prefer only to compare the risks of smokeless tobacco to the risks of nicotine replacement products [48]. The expressed preference to compare the lower risks among lower risk products is an example of how the prevailing framing ideologies have changed from the days of the 1964 Surgeon General’s Report and *Smoke Signals* [20] when the deadliness of cigarettes was stressed as a matter that set the product apart from all others. This blind spot in the literature suggests that some positions can unintentionally bias thinking in one direction.

**Fig. 1** Harm Minimization Continuum (Adapted from Nutt et al 2014 [65])

### Concerns about gateways, brain damage, and addiction as serious harms?

If the direct chronic disease harm from less-harmful, non-combustible smokeless tobacco/electronic cigarette/ANDS products is substantially less than from cigarettes/combustibles, those interested in *tobacco* control (broadly defined) have moved on to new arguments against tobacco use of any kind. For example, despite the evidence for a common underlying liability model having replaced the unproven gateway theory, possible causal “gateways” have increased in importance despite as yet unproven hypothetical fears that ANDS will lead more youth to become combustible users than otherwise would be the case [50, 51]. The shared liability model indicates that risk taking behaviors are common in adolescents and often travel together so that the first behavior is less important as a gateway but rather is an indicator of shared vulnerability to engage in a variety of risky behaviors regardless of which one came first (for details see [51–54]). Unfortunately, the mere threat of a gateway can create media headlines of earnest concern and regulatory attention although surveillance must monitor the real concern that very high prevalence of experimental use of smokeless or ANDS could possibly result in more uptake and progression to regular smoking than would otherwise have been the case [52]. The importance of any alleged causal gateway effects would, however, depend upon the absolute and relative magnitude of any such effects.

For regulators and for future re-framing purposes, an operational definition of the U.S. Food and Drug Administration (FDA)-mandated public health standard is needed to provide a big picture perspective. For example, a Markov model includes all the trajectories (stocks and flows into and out of specific states) of the different product use patterns by groups within the whole population, both users and non-users [53]. If only 5 % of triers of ANDS or snus were *caused* to become lifetime smokers over and above those who would have become smokers anyway and 10 % of potential and current smokers were displaced from becoming smokers, then the overall net effect on the population is to prevent smoking rather than recruit smoking (i.e., an off-ramp rather than an on-ramp or gateway). But, if the large majority of the entire population of youth became triers (70 or 80 %) of ANDS or snus and were to then go on to regularly smoke cigarettes *because* they had first used these products, then that would indicate a serious concern (but, to date, implausible). No research supports the existence of such an effect [51]. What if 70 % or 80 % of ANDS or snus triers (a) did not move on to cigarettes or (b) would have smoked cigarettes even if they had never tried ANDS or snus? (cf. [54]) That would indicate that the *causal* trajectory issues would be

of relatively minor concern under most circumstances. The data on snus is clearest, and in the European review, [33] which seemed motivated to emphasize any evidence for on-ramp effects, concluded, “The Swedish data do not support the hypothesis that smokeless tobacco (i.e., Swedish snus) is a gateway to future smoking.” [33]. In fact over 30 years of experience in Sweden supports that snus has contributed to reductions in mortality from smoking [43].

Note that the gateway hypothesis began with the fear that marijuana would lead to heroin use, and it has not survived as a convincing and current issue and has largely been replaced with a shared vulnerability model [55]. This seems especially clear as marijuana legalization is spreading in the U.S.. The recent trends on use by high school students are, if anything, inconsistent with ANDS looking like a causal gateway to cigarettes [51]. As ANDS trial use (use at least once in the past 30 days) has risen, cigarette use has dropped to historically low levels [56]. Fears of unknown futures, coupled with outmoded 20th century framings need to be rethought, lest they blur the landscape and result in missed opportunities for products which are all legally available to adult consumers and could speed the obsolescence of combusted tobacco use.

Two new arguments have emerged to bolster the older status quo and more extreme (i.e. all or nothing) ideologies of tobacco control. These new arguments depend neither upon the relative harms of different products on mortality nor the concern about a gateway to cigarettes. If not a gateway to cigarettes, some believe that ANDS would be a gateway to severe nicotine addiction, along with concern that nicotine could have substantial irreversible ill-effects on the developing brain or other very severe harms even when decoupled from the deadly smoke of tobacco combustion [57, 58]. Nicotine is not harmless and of course should not be used by pregnant women, just like alcohol, or be used, sold or marketed to minors in any shape or form. But to keep perspective, for anyone already smoking who cannot stop, less harmful delivery modes are considered even NRT use for pregnant women as a last resort. Therefore it seems that nicotine harms should not be exaggerated when legitimate concerns are framed, for example with concerns raised by animal studies but scant human evidence that it causes permanent brain damage when decoupled from all the other toxins in inhaled smoke or that nicotine itself either causes or strongly promotes cancer. There is of course a concern about nicotine from in vitro and animal studies and there is undeniable neuro-adaptation to nicotine as a stimulant, as is the case with any psychoactive chemical [59]. It is too early to assess these arguments and know exactly how they should be integrated into policy at the whole population level. Even if

one accepted very strong concerns about nicotine use per se, the much greater health risks from the use of nicotine in deadly cigarette/combustible smoke does still mean that some forms of nicotine use (NRT, snus, ANDS) are much safer than others. The key issue for public health is what amount of unintended consequences can a new tobacco control framework accept if the overall population benefits of less harmful modes of nicotine delivery are largely quite positive?

Nicotine does have also some positive effects on the brain that may explain its attraction and continued use, for example in increasing concentration, enhancing memory and speeding information processing and reducing stress or to alleviate boredom and low energy. Nicotine can for some users be viewed like other similar classes of stimulants used to increase energy and concentration and focus when drowsy, to ameliorate milder forms of ADHD symptoms, or to enhance memory and acute cognitive performance, and thus be quite appealing to those with underlying or predisposing mental health or cognitive vulnerabilities [60, 61]. One could also imagine that adverse drug effects on the developing brain could also be an argument that would be applicable to simple sugars (widely consumed by the very young in cola beverages and chocolate). Significant numbers of youth do engage in marijuana use, alcohol use, are given or take psychotropic prescription medicines for ADHD, anxiety and depression, all of which could be concerning because of ill-effects on the developing brain but where benefits might be judged to outweigh adverse events or side effects under some circumstances. Reviews of the effects on brain maturation include factors like alcohol, nicotine, caffeine, nutrition, gender, stress, and socio-economic status [58, 62]. Vigilant, prudent policies and enforcement of policies is always needed to protect youth from any and all drugs of potential abuse (e.g. opioids and heroin), but frameworks that selectively exaggerate nicotine fears are to be questioned and may do more harm than good in the long run at the whole population level (i.e., for any smokers who may now want to use nicotine in another form of delivery - NRT, smokeless, ANDS) [31, 32, 39, 42, 51, 53, 54].

#### **A balanced look at absolute and relative harms points to new frameworks for tobacco control**

The overview of leading themes here has focused on images and frames that have helped guide tobacco control as it has dealt with recreational tobacco/nicotine products (see Table 1). We have not discussed in any detail the importance of the introduction and promotion of nicotine replacement products in the 1980s and their more recent acceptance for over-the-counter use and long-term use to promote smoking cessation that has no doubt contributed to re-framings related to nicotine [32,

63, 64]. The change that came about when cigarettes were judged to be highly lethal, when used as intended, and more lethal than a sum of other sources of public health harm was a kind of watershed moment in tobacco control. The emergence of reduced harm products like Swedish low nitrosamine snus, NRT, and ANDS raise critical issues regarding the leading themes of the tobacco control field going forward. The “continuum of risk” can be considered an updated framing that has been proposed to help guide tobacco control efforts [65] (see Fig. 1).

Identifying a theme like “the continuum of risk” is not the same as establishing a detailed framework with which to guide tobacco control. The net public health impact of ANDS will be a complex interaction of many factors at multiple levels of influence. Systems thinking and simulation modeling tools will be needed along with more informative data before we will be able to say how best to maximize the benefits of ANDS as a disruptive technology and minimize the hypothetical harms of ANDS to the population as a whole, including users and non-users and especially youth [31, 42, 51, 53]. Regulators and policymakers must keep the big picture in mind when framing key messages to accurately inform consumers.

#### **“Cigarette control” remains the priority as does the de-normalization of cigarettes/combustibles**

The arguments for controlling tobacco/nicotine products should not be uniform across all products, because the risks are not uniform, but dramatically different. If the *Smoke Signals* media handbook [20] were honestly rewritten for snus or ANDS, these products would be seen as among the least risky of popular recreational drug products. When the cigarette control movement learned to oppose the powerful pro-tobacco arguments with evidence-based symbolically-charged responses, it was a large leap forward for cigarette control. When these arguments are misapplied to products that do not approach cigarettes in the damage caused to users and bystanders, it is fallacious, misleading, and compromising to credibility. While it has been feared that ANDS will re-normalize smoking, it could be likelier that the availability of satisfying, much less dangerous cigarette substitutes will act to make it be all the more abnormal for someone to be smoking deadly cigarettes/combustibles.

Those who want to advance tobacco control should appreciate that (a) cigarette/combusted tobacco control remains the highest priority and (b) the arguments against the use of products like vape and snus should not be grounded inappropriately in broad-based all or nothing anti-cigarette arguments. Tobacco control arguments should be proportionate to the absolute and relative

harms of each class of products, especially the most deadly combustible products, and be science-based [31, 42]. And, we should work hardest to reduce demand for and the appeal of cigarettes/combustibles [66, 67] which remain highly lethal when used as intended and deadly to more individuals each year than heroin, cocaine, alcohol, AIDS, fires, homicide, suicide and automobile crashes COMBINED. As tobacco control looks to the future, a more complex road map (a framework rather than just an assemblage of themes) is needed to guide arguments, strategies, interventions, and policies to most rapidly eliminate the preventable deaths, inordinate disease burdens, and suffering at the whole population level [53].

It has been said by systems scientists “for every complex problem there is a simple solution ... and its wrong.” [68–70]. An integrated and overarching framework is needed within which the complex patterns of poly-tobacco and nicotine use behavior must be viewed [42, 53]. For example, an emerging Markov model framework has been proposed to identify all shifts in the patterns of tobacco use that can alter the ultimate population impact [53]. Given an estimated 1 billion preventable premature deaths worldwide in the 21<sup>st</sup> century, the stakes are enormously high to do more. Sharper, unambiguous themes and messages for different product classes would enhance accurate consumer, policymaker, advocacy and stakeholder knowledge, attitudes, beliefs and actions. Aligned common ground about the relative harms of the different classes of tobacco and nicotine delivery products would more powerfully drive motivated consumer behavior change in the direction of reducing the death and disease burden, overwhelmingly caused by use of lethal combustibles/cigarettes. Leading themes, frames, messages, and slogans all really matter.

## Conclusions

The last 50 years of tobacco control in the U.S. have regularly engaged issues of absolute risk and harm reduction, but have done so in varying ways (see Table 1). The recognition that cigarettes were deadly when used as intended and more lethal than a number of other unsafe products combined was influential and important in the progress of tobacco control. In subsequent years, other forms of tobacco use were treated as similar to cigarettes in issues raised [42]. It is important to make clear distinctions between the classes of tobacco/nicotine products as they differ substantially in risk to the user and to focus tobacco control efforts on reducing the use of cigarettes and other combustible products (see Fig. 1). Complex models [42, 53] should be employed in tobacco control in order to not treat products with

large differences in risks as if they are the same [31]. A new reframing of leading themes can align action plans to more powerfully and rapidly achieve population-level benefit and minimize harm. The goal of updating the framing with a new synthesis of management of all forms of nicotine delivery is to eliminate use of the most appealing, addictive and deadly form of tobacco delivery in our lifetime - the smoking of combustible tobacco products - and thus expeditiously prevent the premature deaths of 1 billion people projected to occur worldwide by 2100, if the contentious debate is not resolved.

Health information

Public health ethics

### ABSTRACT

The United States provides an example of a country with (a) legal tobacco/nicotine products (e.g., snus, other smokeless tobacco, cigarettes) differing greatly in risks to health and (b) respected health information websites that continue to omit or provide incorrect differential risk information. Concern for the principles of individual rights, health literacy, and personal autonomy (making decisions for oneself), which are key principles of public health ethics, has been countered by utilitarian arguments for the use of misleading or limited information to protect public health overall. We argue that omitting key health relevant information for current or prospective consumers represents a kind of quarantine of health relevant information. As with disease quarantines, the coercive effects of quarantining information on differential risks need to be justified, not merely by fears of net negative public health effects, but by convincing evidence that such measures are actually warranted, that public health overall is in imminent danger and that the danger is sufficient to override principles of individual autonomy. Omitting such health relevant information for consumers of such products effectively blindfolds them and impairs their making informed personal choices. Moral psychological issues that treat all tobacco/nicotine products similarly may also be influencing the reluctance to inform on differential risks. In countries where tobacco/nicotine products are legally sold and also differ greatly in disease risks compared to cigarettes (e.g., smokeless tobacco and vape), science based, comprehensible, and actionable health information (consistent with health literacy principles) on differential risks should be available and only reconsidered if it is established that this information is causing losses to population health overall.

This commentary focuses on the example of smokeless tobacco and cigarettes in the United States. It arises out of revisiting a report on information on major health websites in 2003 (Kozlowski & O'Connor, 2003) which found considerable misinformation or disinformation on relative risks on these sites. Improvements have been identified, but concerns continue about the lack of information on significant differential health risks between cigarettes and smokeless tobacco. The ethical arguments presented can be applied to any country where tobacco/nicotine

products (including vape or electronic cigarettes) with differential health risks are sold and agencies and organizations can provide health information related to these products.

### Differential harm from smokeless tobacco products and cigarettes

The American public is unaware of dramatic differential harms from different legal tobacco/nicotine products (Kiviniemi & Kozlowski, 2015). Conflicting headlines and media reports contribute to the compromise of public awareness (Berman, 2008; Eversman, 2015; Liu et al., 2015). The National Cancer Institutes (NCI) national survey on health information evaluated public beliefs about how smokeless tobacco (SLT) risks compared to cigarette risks and asked: "In your opinion, do you think that some smokeless tobacco products, such as chewing tobacco, snus

and snuff are less harmful to a person's health than cigarettes?" Only 9.4% of the public answered "yes" (Kiviniemi & Kozlowski, 2015). This small proportion of people aware of any difference in risk is of course not evidence that they comprehend the magnitude of the risk differential, which would be necessary to exercise personal autonomy.

The Surgeon General has concluded that combustible tobacco products are by far of greatest concern for public health (United States Public Health Service. Office of the Surgeon General, 2014). Though not safe, there is no scientific doubt that manufactured smokeless tobacco (SLT) products in the U.S. (and notably, low nitrosamine Swedish snus) are dramatically less dangerous than cigarettes to life long users of each product (Benowitz, 2011; Levy et al., 2004; Piano et al., 2010; Scientific Committee on Emerging and Newly Identified Health Risks, 2008; Stratton, 2001). In the U.S., the essentially complete avoidance of lung cancer risks and other respiratory disease risks (Scientific Committee on Emerging and Newly Identified Health Risks, 2008) alone would reduce mortality by 54.8% (Center for Disease Control and Prevention, 2015). The American Heart Association review panel concluded: "Data from international, European, and US studies overwhelmingly demonstrate that compared with ST users, active smokers are at much greater risk for CV [Cardio vascular] morbidity and mortality and have shorter life spans." A European review judged that the cardio vascular disease risk reduction is at least 50% compared to smoking (Scientific Committee on Emerging and Newly Identified Health Risks, 2008). Overall estimates of risk reduction from snus versus cigarettes have been 90% or more (Lee, 2013; Levy et al., 2004).

### Past and current health website deficiencies

In 2003 (Kozlowski & O'Connor, 2003) the information on the Centers for Disease Control and Prevention (CDC) and the Substance Abuse and Mental Health Services Administration (SAMHSA) web sites was assessed on the popular question of whether SLT was safer than cigarettes. These sites had erroneously informed that SLT was as dangerous as cigarettes. For organizations committed to health information quality (Office of Management and Budget, 2002), this was considered an ethical lapse and examples of health misinformation or disinformation.

In November 2015, inspection of major health information web sites of CDC (Centers for Disease Control and Prevention, 2015), SAMHSA (Substance Abuse and Mental Health Services Administration, 2015), American Cancer Society [ACS] (American Cancer Society, 2015), NCI (National Cancer Institute, 2015) and the Mayo Clinic (Mayo Clinic, 2015)) found three types of examples of information on SLT, but no to modest efforts to inform consumers of the significantly lower risks compared to cigarettes for lifelong users (see Table 1.) The Mayo Clinic perpetuates the error found in 2003 with the headline: "Chewing tobacco: Not safer than smoking." ("Chewing tobacco" refers to all SLT.) CDC, SAMHSA, and NCI provide no cigarette comparative risk

information that might help correct public misunderstandings. ACS provides some comparative information: "Smokeless tobacco products are less lethal than cigarettes: On average, they kill fewer people than cigarettes." Consumers might also value learning, and individual rights and personal autonomy require they be informed of, the considerable magnitude of difference in harms.

### Information on comparative risks is commonplace—except for tobacco/nicotine

If science learned that one type of alcoholic beverage caused 3 in 5 regular users to die prematurely, losing 10 years of life (Jha et al., 2013), while another alcoholic beverage caused 95% or even 9.5% fewer premature deaths, consumers would want to know which legal product was which. (With alcohol the especially dangerous item would be banned, but assume that, as with current Food and Drug Administration (FDA) tobacco law, this is impossible.) It would be scandalous, even criminal, to keep such facts from consumers. Yet, such facts are being kept from adult consumers of legal tobacco/nicotine products (Kiviniemi & Kozlowski, 2015) either by not informing or actively misinforming consumers (Kozlowski & O'Connor, 2003). It is as if tobacco consumers were blindfolded and not allowed to see dramatic differences in harm from different products.

In the U.S. there is a National Action Plan to improve health literacy (U.S. Department of Health and Human Services, 2010) and all Federal agencies are required to ensure the "quality, objectivity, utility, and integrity of information disseminated" (Office of Management and Budget, 2002). "Health literacy is the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions" (U.S. Department of Health and Human Services, 2010). The importance of informing consumers about meaningful differential risks of various products (e.g., crash worthiness of cars) and the direct risks of unsafe products (e.g., over the counter and prescription drugs) is widely accepted in consumer protection laws and in product liability litigation, and it is viewed as negligent to fail to do so (Cornell University Law School, 2015). However, informing consumers of differential harms from various tobacco/nicotine products has been controversial, out of fear that this personal health information may have net negative effects on population health as a whole (Eversman, 2015; Gray & Henningfield, 2006; Hatsukami, Lemmonds, & Tomar, 2004; Maziak, 2014; McKenna, Pechacek, & Stroup, 2003; Tomar, Fox, & Severson, 2009; Watson & Forshaw, 2015).

The FDA is doing little to strip off the blindfold, even though the Director of its Center for Tobacco Products has acknowledged a significant continuum of risk (Zeller, 2012) and the differences in risks are dramatic (Nutt et al., 2014). FDA has a mandate to do public education on tobacco; however, FDA law fundamentally protects cigarettes and smokeless tobacco for adults and forbids banning. Marketing is allowed, and the law discourages requiring any product changes that could encourage contraband markets.

Table 1

Summary of comparative information on the harms from cigarettes (Cig) versus smokeless tobacco (SLT) from current notable institutions.

	Message type	Site	Lung cancer	Respiratory disease	CVD	Health literacy quality
1	SLT = Cig Harm	Mayo (Mayo Clinic, 2015)*	No info	No info	No info	Falsehood
2	SLT Harm Only	CDC (Centers for Disease Control and Prevention, 2015) NCI (National Cancer Institute, 2015), SAMHSA (Substance Abuse and Mental Health Services Administration, 2015)	No info	No info	No info	Correct on SLT harms; no comparison with smoking
3	SLT Harm less lethal	ACS (American Cancer Society, 2015)	No info	No info	No info	Correct on SLT, Limited comparisons with smoking

\* The Mayo Clinic website changed on April 2, 2016, substituting a "not a safe product" heading for the previous "not safer than cigarettes" heading.

(Altria which controls over half of the national cigarette market actively supported this law (Wilson, 2009).) FDA law even has a unique provision for tobacco (United States Code, 2009) which forbids marketing by manufacturers of any reduced harm product information unless it has been proven *before marketing that such marketing will not have an adverse effect on population health*, a near impossible task, a barrier that no product has yet surmounted, and one not imposed on other FDA regulated product categories. FDA, despite its mandate to engage in public education, has to date transferred the responsibility for providing accurate life critical consumer product information to the commercial marketing of tobacco companies. But such a high regulatory standard, likely combined with cigarette focused companies benefiting from not surmounting it, contributes to smokers being ill informed about product risks. When the most deadly “disease” (smoking) is protected by FDA, it is as if needle exchange programs had to prove no negative public health effects before being implemented while heroin given via dirty syringes was sold over the counter.

It is interesting to speculate how the FDA and health authorities might treat a new pill that dramatically reduced the risk of lung cancer. We think the focus would be on allowing the company to market this pill, with relatively little concern about the possible negative effects if smokers were to reduce their desire to stop smoking because of the availability of the pill and perhaps experience continued risks of other respiratory or cardiovascular disease. There would likely not be as much attention to possible net effects on population health.

### Large vs. negligible harm reduction

Public health concerns arising from reduced risk claims (Stratton, 2001) probably arose to try to prevent repeating the public health tragedy of “low tar” cigarettes which encouraged smokers to continue smoking and yet had negligible, if any, effects on reducing smoking caused diseases (National Cancer Institute, 2001). *Again: Lower tar cigarettes did not significantly reduce the harms of smoking!* Public health losses were caused by consumers being misled in a way that resulted in more dangerous behaviors more people smoking than would have otherwise been the case. Ironically, the same manner of deleterious effect could flow from allowing consumers to overestimate the risks of truly less hazardous products, causing them to avoid switching to a product that they do not appreciate is much less hazardous. The error of presenting products with no meaningful risk reduction as if they were safer cannot be redressed by committing the equally life threatening error of presenting products with large risk reductions as if they are not safer or by concealing this information.

### Unjustified health information ‘quarantine’

Public health ethics permits suppression of individual rights to protect public health, as with required vaccinations and quarantines (Cetron & Landwirth, 2005; Kass, 2001, 2004). But these exceptions to the rule on individual autonomy demand strong justification, not just suspicions, even plausible ones, that it could be warranted. Ethical analysis of public health decision making on quarantines emphasizes the principles of proportionality and effectiveness. It is worth quoting Kass (2001) because it illustrates both the issues and the complexity of the current predicament:

Programs that are coercive should be kept to a minimum, should never be implemented when a less restrictive program would achieve comparable goals, and **should be implemented only in the face of clear public health need and good data demonstrating effectiveness**. Nonetheless, we are a pluralistic society, including with regard to our notions of ethics. Different

states and communities will decide differently which public health activities are appropriate and which are overly burdensome. [emphasis added]

Part one of Kass's point is that coercive actions need prior justification from a *clear public health need* and *good data demonstrating effectiveness*. For tobacco control, (a) the most urgent public health need is to reduce the use of combustible tobacco, especially cigarettes (United States Public Health Service, Office of the Surgeon General, 2014) and (b) good data is lacking to demonstrate that restricting accurate information or engaging in active misinformation on reduced harm products has any good effects on population health. Similarly, U.S. rules on information quality do allow standards to be “waived temporarily” only under “urgent situations (e.g., imminent threats to public health or homeland security)” (p. 8485) (Office of Management and Budget, 2002). It is simply preposterous to think the current evidence base demonstrates there is an “imminent threat” to public health in this instance.

But part two of Kass's point is that community standards also influence the appropriateness of public health activities. The demonization of tobacco/nicotine products and the tobacco industry may have distorted public health principles by *acting as if all tobacco products should be banned* (Proctor, 2013). A moral outrage has characterized views on tobacco which has been much greater than for other unsafe, legal and even illicit consumer products (MacCoun, 2013). Harm reduction principles have been readily embraced for many decidedly unsafe commercial products (cars, pharmaceuticals, alcohol), and for behaviors often illicit or morally objectionable to others, yet cigarettes and tobacco have been treated quite differently.

### Ethical analysis, moral psychology, and anti-vice inclinations

For many people, when cigarettes were judged as (1) the largest single cause of preventable death and disability, (2) lethal when used as intended by manufacturers, and estimated to be more deadly than the next several most dangerous activities combined, they crossed a line (American Cancer Society, 1987; Warner et al., 1986). When the behavior of cigarette companies so infuriated the public, these companies became seen as evil, and this encouraged an absolutist, anti vice response (Berridge, 2013; Courtwright, 2012; McCambridge, 2015). (The matter of the predations of tobacco industry marketing is very distinct from respected health information websites trying to improve consumers' knowledge and should not be confused.) Detailed ethical analyses of tobacco/nicotine harm reduction are available (Chapman & Daube, 2015; Hall & Forlini, 2015; Kozlowski, 2002, 2015b; Kozlowski & Edwards, 2005; Kozlowski & O'Connor, 2003; McCambridge, 2015; Royal College of Physicians, 2007; Savitz, Meyer, Tanzer, Mirvish, & Lewin, 2006). They have employed standard issues like beneficence, non maleficence, justice, and autonomy. In an area charged by views of vice and improper behavior, it important to consider moral psychological perspectives that point to strong moral emotional reactions to violations of a sense of purity, respect for authority, and a concern about community standards (Haidt, 2007). Such violations can trigger emotionally charged moral reactions (disgust and contempt) for tobacco use and even to the use of much less harmful tobacco/nicotine products (Alderman, Dollar, & Kozlowski, 2010; Kozlowski, 2013, 2015b).

### Utilitarian principles and evidence for coercive actions

In a CDC response (McKenna et al., 2003) to the 2003 critique (Kozlowski & O'Connor, 2003) of misleading information (indicating that SLT was not safer than cigarettes), the authors, in keeping

with arguments from the Institute of Medicine review (Stratton, 2001), assert several ways in which SLT could cause public health losses:

Even if some smokers who switch to SLT do reduce their individual risk, it is plausible that overall population health risk would increase if SLT were promoted as a potential reduced exposure product. This conclusion assumes that (a) some smokers who would have otherwise quit using tobacco would switch to SLT or continue to smoke and use SLT; (b) the number of lifelong SLT users would rise as a result of increased youth SLT initiation; (c) the number of smokers would rise as a result of increased youth SLT initiation with subsequent switching to cigarette use; and/or (d) some former smokers would relapse, believing SLT a less hazardous way to consume tobacco. (p. 194)

Theoretical concerns are not enough, however, no matter how plausible or how many, to justify information quarantine. Both (a) *evidence* of a problem and (b) *evidence* that the deception/evasion is important in dealing with the problem are needed. The rights of SLT users to have information that might prevent their sometimes smoking or even switching to cigarettes should not be so readily waived. Accurate science based, comprehensible, and actionable health information on comparative risk is also not strictly a “promotion” of reduced risk products as done by a manufacturer, rather it is a contribution to health literacy that in the context of systematic tobacco control efforts might “plausibly” even produce public health gains. Anyone, no matter their current use of tobacco or nicotine products, could value being knowledgeable about differential product risks for themselves or their loved ones.

“Gateway effects” whereby SLT *causes* later smoking has been a topic of major interest in tobacco control and provides an example of the small magnitude of confirmed adverse effects as well as failures to find effects (e.g., Kozlowski, O'Connor, Quinio Edwards, & Flaherty, 2004; O'Connor, Flaherty, Quinio Edwards, & Kozlowski, 2003; Tomar et al., 2009). The political power of gateway fears is greater than their scientific usefulness (Bell & Keane, 2014; Kleinig, 2015; Phillips, 2015). For many drug researchers, causal gateway models have been abandoned in favor of an appreciation that circumstances influence which drug products youth start with (Degenhardt et al., 2010) and that individual and contextual characteristics make some individuals at higher risk (and others at lower risks) of using drug products (Vanyukov & Ridenour, 2012). Certainly, a mere unproven hypothesis does not provide an ethical basis for information quarantine.

A recent review of longitudinal research shows that overall non smoking adults (including SLT users) are unlikely to become cigarette smokers (Tam, Day, Rostron, & Apelberg, 2015). A study in military recruits indicated the greatest risk of non smoking SLT initiators becoming smokers (Haddock et al., 2001), but it is noted that context may reduce generalizability (Tam et al., 2015). Even then, the *minority* (about 27%) of SLT tobacco users turned to smoking, compared to about 13% for those who had not used SLT (Haddock et al., 2001). A long term longitudinal study has found great stability in use of SLT or cigarettes and that beliefs about the risks of these products influence use (Macy, Li, Xun, Presson, & Chassin, 2015). National patterns of e cigarette use (Delnevo et al., 2015) or smokeless tobacco use (Tomar, Alpert, & Connolly, 2010) do not give evidence of net public health losses in the area of tobacco use and shifts to cigarettes that might help justify a quarantine of information on reduced risk products. Indeed, it seems simply absurd to justify not giving consumers sufficient information to make informed decisions based on the view that previously ill informed consumers may have made poor decisions or that well informed consumers might make the “wrong” decision. Sweden provides an example of finding *no evidence* of

any noteworthy causal gateway effects from snus to cigarettes, despite a close look for it (Foulds, Ramstrom, Burke, & Fagerstrom, 2003; Scientific Committee on Emerging and Newly Identified Health Risks, 2008). Although the U.S. might be different (Tomar et al., 2009), evidence from Sweden should be weighed more heavily than hypotheses that lack an ethical basis and a persuasive evidence base. Even if a smoker switching to SLT later in life would have smaller effects on disease reductions, it is clear that those who would stop smoking by 30 or 40 are likely to see dramatic reductions in smoking caused disease to near never smoking levels (Jha et al., 2013). Given policy options available to nudge tobacco use behavior (such as differential taxation, marketing and information) (Jha & Chaloupka, 1999; Kozlowski, 2007, 2015a, 2016), a more reasonable approach to any apprehension of risk should be based on the application rather than the denial of the principle of health literacy. Research on snus use in Norway has found that providing accurate risk estimates to smokers can result in increased quit rates for smoking (Lund & Lund, 2014; Lund, 2012).

### Care for autonomy and individual rights

If accurate information on relative risks of various products helps even a few users of cigarettes to move from or stay away from cigarettes, it is preferable to a context of providing no information, misinformation, or disinformation to consumers of these products (Kiviniemi & Kozlowski, 2015; Kozlowski, O'Connor, & Edwards, 2003). An ethical basis for public health communications to establish health literacy, one focused on individual autonomy and accurate information (which FDA could help determine), should be required (Office of Management and Budget, 2002). Denial of information to consumers could have similar effects as the historic efforts of cigarette companies to mislead smokers about disease risks and to fight against health information on cigarette advertisements and packaging. While the industry may have been motivated by profits and the health agencies had different motivations, the negative effects for individual users could be the same. Evidence is growing that snus can aid smoking cessation (Hatsukami, Severson, et al., 2015). Use of lower harm products (including vape) may not be for everyone, and the ability of these to supplant smoking remains to be shaped and delineated. If the user does not enjoy the product, it is unlikely to be used for long (Kozlowski, 1982; Kozlowski, Heatherton, Frecker, & Nolte, 1989; Saddleson et al., 2016). Personal satisfaction with any product is important (Hatsukami, Vogel, Severson, Jensen, & O'Connor, 2015). But the blindfolding of consumers delays such transitions and impedes efforts to develop products that could more effectively replace cigarettes.

For a very much lower risk product (Nutt et al., 2014), it could take an impossible increase in users to match public health harm of cigarettes (Kozlowski, Strasser, Giovino, Erickson, & Terza, 2001). For small reductions in risk (e.g., 10%), negative population health consequences are far likelier. How many recreational users of snus (Hatsukami, Severson, et al., 2015) or vape would avoid cigarettes completely could be influenced by accurate information and appropriate marketing. Until differential marketing according to risks is actually implemented (Branston & Sweanor, 2016; Chaloupka, Sweanor, & Warner, 2015; Kozlowski, 2007), it is hard to know the impact that products like SLT or vaping could have on cigarette use. But it is unethical as well as lacking a scientific basis to maintain that there is so little reason to believe that consumers would respond to adequate information on differential risks that there is no point in even considering removing their blindfold.

Current FDA tobacco rules and educational practices on prominent web sites represent a swamp of precaution that contributes to preventing broader awareness of products that

are known to be dramatically safer than cigarettes. Efforts should be made to educate the public about the nature of risks from different classes or types of tobacco products (Biener, Bogen, & Connolly, 2007; Biener, Nyman, Stepanov, & Hatsukami, 2014; Kiviniemi & Kozlowski, 2015) and how burning and inhalation makes a difference (Strasser et al., 2011). Simple but effective graphic tools like traffic light systems can be employed (Strasser et al., 2011). A growing evidence base on e cigarettes indicates that they too are dramatically less dangerous than cigarettes (Hajek, Etter, Benowitz, Eissenberg, & McRobbie, 2014; McNeill, Calder, Hitchman, Hajek, & McRobbie, 2015) (As with vape, long term epidemiology of the new imaginary wonder pill for lung cancer would also be a work in progress; since the 1970s, 35 prescription drugs have been removed from the market (ProCon.org, 2014).) So once again, a mere hypothesis of a potential problem, one lacking an evidentiary basis, is not sufficient to justify blindfolding consumers.

### Complexities of ethical analysis of public health police powers

Coercive measures on behalf of public health are also called police powers. Quarantines to prevent the spread of disease are not the only example of public health police powers. The principles of autonomy, privacy, liberty and personal property can conflict with actions to try to protect public health. We have emphasized issues arising from public health efforts to prevent net harm to population health. A classic work on public health law (Gostin & Wiley, 2016) does recognize that these questions must always be posed:

... whether a coercive intervention truly reduces aggregate health risks and what, if any, less intrusive interventions might reduce those risks as well or better? Respect for the rights of individuals and fairness toward groups of all races, religions, and cultures remain at the heart of public health. (p. 11)

But it should be admitted that ethical arguments have been based on principles other than aggregate harm to the population. Some ethicists prefer to use paternalism (or parentalism) to justify protecting even mentally competent, adult citizens from themselves 'for their own good.' See Gostin and Wiley (2016) for a discussion of this and other perspectives. In contrast, a focus on the importance of liberty even in the face of utilitarian costs opposes paternalism (e.g. Berlin, Hardy, & Harris, 2002). We prefer to give strong emphasis on the principles of personal autonomy and individual rights while not ignoring utilitarian issues which is sometimes called a 'rule utilitarian position.' Also, although we have focused on issues pertaining to adult consumers of legal products, we see no case for keeping comprehensible health information about products away from those who may not be legally able to purchase these products and do not know how that could be done if made available to adults.

### Summary

Table 2 outlines the main ethical and moral psychological issues discussed. Concerns for some adverse public health effects of harm reduction products such as SLT and vape are reasonable and worth trying to minimize, but there is no current evidence that such products actually represent an imminent danger to public health overall and that withholding information about relative risks is an effective way to promote overall public health. Efforts to discourage the use of tobacco/nicotine products need not be reduced, but should be done in a harm proportionate way. Telling consumers that all product options are as bad as cigarettes is untrue and almost certainly as deadly for users as telling at risk populations that condom use affords no protection. Giving

**Table 2**

Key ethical perspectives on providing accurate health information to consumers of unsafe legal consumer products.

1	Health Literacy and respect for autonomy are critical
2	Utilitarian principles (greatest good for the greatest number) support concern about science-based, comprehensible, and actionable information that is shown to harm public health
3	To be ethical, coercive measures (e.g., information quarantine) require more than plausible concerns, but actual prior evidence that the measures are proportionate and effective in protecting public health
4	Moral psychological reactions (disgust and contempt) arising from the views of and nature of tobacco products and the behavior of industry violate 'community standards,' 'proper respect for authority' and 'a sense of purity,' and promote acting as if all tobacco/nicotine should be banned
5	Omitting accurate health information that might guide behavior and decisions of any (even a few) users of legal products is inconsistent with health literacy and respect for autonomy
6	To achieve utilitarian goals, other product differentiating tobacco control/marketing methods should be exhausted before deceptive or evasive health information are employed—if they ever are included as an option

accurate information does not guarantee that a problem will be solved, but it stands the ethical rules on their head to not value health literacy and information quality (Office of Management and Budget, 2002). That reduced harm products are not absolutely 'safe' and more dangerous than using no tobacco/nicotine product does not justify keeping potential consumers of legal products ignorant about this information any more than such arguments would for any other product or activity.

For evidence based health organizations to provide accurate information on the relative harms of tobacco/nicotine products does not even carry with it any concerns that apply to manufacturers embedding relative risk information in lifestyle advertising designed to recruit customers. The straight forward principles of harm reduction should be as uncontroversial for tobacco products as they are for alcohol, cars, air travel, children's clothing, sexual practices, electrical goods and other goods and activities until such time as there is compelling, proportionate evidence of imminent danger to public health overall that would ethically justify promoting health illiteracy with respect to these legal products. Even then, some ethicists would never support deceptive information as an appropriate public health option (Bok, 1978) and the risk of loss to credibility would be earnestly avoided.

### Acknowledgments

LTk is funded as an investigator on two FDA NIH grants, one on little cigars and one on electronic cigarettes, but this report was not funded.

### Conflict of interest

No financial disclosures to report. The authors have each written before in support of tobacco harm reduction.

Harm reduction

## ABSTRACT

**Background:** Tobacco harm reduction involves advocating the use of a less harmful alternative to smoking for those users who are unwilling or unable to quit. The net effect of such an approach is unclear as it may create opposing incentives. Although some smokers may substitute toward this less harmful alternative, it may reduce the incentive to quit by undermining public health efforts and may act as a gateway to smoking. This research paper aims to answer the question: Does the availability of a less harmful alternative to smoking lead to cessation? To explore the opposing incentives created by a harm reduction approach to smoking cessation, I focus on the role of snus, a popular smokeless tobacco product in Scandinavia that is widely used in Sweden.

**Methods:** This paper exploits a quasi-natural experiment to examine the net effect resulting from these opposing incentives. While two Scandinavian countries, Sweden and Finland, joined the European Union (EU) in 1995, Finland was subject to a pre-existing EU ban on oral tobacco products while Sweden received an exemption. A difference in differences framework is used to estimate the change in the smoking rate in Finland due to the implementation of the ban. A secondary analysis uses Finnish smoking data to test for a structural break in trend.

**Results:** In the post-ban period, smoking was 3.47 percentage points higher in Finland relative to what it would have been in the absence of the ban.

**Conclusion:** The availability of snus, a less harmful alternative to smoking, appears to have had a positive impact (reduction) on the smoking rate. Offering acceptable alternatives to cigarettes is critical in reducing smoking prevalence.

## Introduction

Tobacco harm reduction involves advocating the use of a less harmful alternative in lieu of complete abstinence for those smokers who are unwilling or unable to quit. The goal of such an approach is to lower the smoking rate by providing an acceptable substitute to current smokers. Many advocates of tobacco harm reduction cite the Swedish Experience, a term used to refer to Sweden's relatively high rate of tobacco consumption, but low level of smoking related disease. This phenomena is attributed to the widespread use of snus and suggests that the availability of this less harmful alternative is key to Sweden's low smoking rate (see Fagerström & Schildt, 2003).

Snus is a form of tobacco that is used orally and offers an alternative to smoking. It has nicotine content similar to that of cigarettes

(Roth, Roth, & Liu, 2005), but it differs from cigarettes in several ways which makes it an attractive substitute. It is considered to be less harmful than smoking (Nutt et al., 2014; Royal College of Physicians, 2007), and poses fewer externalities as there is no second hand smoke. Despite the benefits that may arise from advocating the use of snus as an alternative to cigarettes (and promoting it as a substitute), many remain sceptical of a doing so as such an approach may create opposing incentives (see Savage, 2007).

The availability of a less harmful alternative to smoking may act as an incentive to increase nicotine consumption among smokers and may act as a gateway to smoking (Milikian and Hoffmann, 2009). A product that allows cigarette users to continue nicotine intake in areas where smoking is prohibited moderates the incentive to quit tobacco use altogether and may undermine public health efforts, reducing the effectiveness of policies aimed at decreasing smoking. In addition, as Savitz, Meyer, Tanzer, Mirvish, and Lewin (2006) notes, there is concern that there may be widespread misunderstanding resulting from a harm reduction strategy whereby the public may mistake "safer" for "safe". A

product marketed as a less harmful alternative to cigarettes may attract users who would have otherwise abstained. These new users, once addicted to nicotine, may ultimately progress to cigarette use. Both scenarios suggest that the availability of snus would have a negative effect (increase) on the smoking rate. However, advocates of tobacco harm reduction believe that the availability of a less harmful alternative, such as snus, provides an incentive for current smokers to substitute away from cigarettes and toward the less harmful good. This would lead to a decrease in the number of smokers, and ultimately, a reduction in negative health effects due to tobacco use (Rodu & Godshall, 2006).

Prior research studies examining the role of snus in smoking cessation or uptake primarily rely on survey data. Several studies using survey data from Norway and Sweden find that many respondents report using snus to help quit smoking. Lund, Scheffels, and McNeill (2011) review seven cross-sectional data sets and find that the quit ratio for smokers who used snus was generally significantly higher than for those who did not. Stenbeck, Hagquist, and Rosén (2009) study cigarette uptake and quit behaviour attributable to snus use among Swedish males in the 1990s. They find that behaviour varies by age group with the younger cohort (age 16–44) having six quitters per smoking starter attributable to snus. Among the older cohort (age 45–84), the difference was more modest with approximately two quitter per starter. Some research has found that snus use may reduce smoking initiation. Ramström and Foulds (2006) find that smoking uptake was lower for those that used snus than for those who had not. Among primary snus users, 20 percent initiated daily smoking while 47 percent of non-users did so.

Ramström and Foulds (2006) also compared the effectiveness of snus with other nicotine replacement therapies as a smoking cessation aid. They found that 66 percent of Swedish men who used snus were able to quit smoking compared to only 47 percent of those using nicotine gum and 32% of those using the nicotine patch. Lund, McNeill, and Scheffels (2010) report consistent results among Norwegian males, finding that would be quitters who use snus were more likely to be successful than those who used other medicinal nicotine products. They also note that those who use snus were more likely to remain nicotine dependent and continue use long term.

Although survey data is useful, determining the net impact on the smoking rate due to the use of this product and assessing the external validity of the findings is challenging. Prior research has been unable to directly address the competing incentives created by a harm reduction approach to smoking cessation. This research paper aims to determine if the availability of a less harmful alternative to smoking reduces the overall prevalence of smoking. Within this context, I focus on the impact of the availability of snus. As data on introducing snus to a market is not available, I undertake an alternative approach. I exploit a quasi-natural experiment to determine the effect of removing snus from a market, in effect limiting the availability of this less harmful alternative, and explore the subsequent change in the smoking rate.

The European Union (EU) implemented a ban on oral tobacco products in 1992 and Finland was forced to ban the sale of snus when it joined the European Union in 1995. Joining the EU and the resulting policy change in Finland provides a means to evaluate the effect on the smoking rate due to limiting access to a less harmful alternative.

## Empirical methods

### Data

Data on smoking prevalence was obtained from the World Health Organization (WHO) “European Health for All” database.

This database contains an array of core health statistics including demographics, health determinants, risk factors, and health care resources and expenditures for 53 member states. Data on smoking prevalence by age group for Finnish males and total snus consumption (estimated through retail sales tax) was obtained from a statistical report, which was compiled by The European Smokeless Tobacco Council in Brussels from data collected by Finland’s National Public Health Institute (NPHI). The NPHI collects the data through a yearly survey that gathers information on the health status and health behaviour of the Finnish population.

### Differencing analysis

In 1992, the European Union implemented a mandatory ban on all oral tobacco products, except those intended to be smoked or chewed (i.e., cigarettes and whole leaf tobacco). This ban prohibited the sale and advertising of moist snuff and snus (Council of the European Communities, 1992). The rationale for the ban was to protect public health by limiting uptake of a potentially harmful product (European Commission, 2012). When Sweden and Finland joined the EU in 1995, both countries were subject to this ban. Sweden applied for and received an exemption, and remains the only country in the EU where the sale of snus is legal. Finland did not apply for an exemption and upon joining the EU was required to implement a ban on the sale of snus. Using these two similar countries, it is possible to exploit the differing response to the ban to investigate the effect of banning snus on the smoking rate.

Key to successful implementation of the difference in differences methodology is finding an appropriate control. Although Sweden and Finland differed in response to the proposed ban, they share many similarities which make Sweden a reasonable control for Finland. Finland and Sweden are both northern welfare states and share many health and societal policies. Both Finnish and Swedish are the national languages of Finland. Both countries joined the EU at the same point in time and would have experienced similar political, social, and price effects as a result of the change. With the exception of the snus ban, public policy regarding tobacco is very similar between these two countries (Patja, Hakala, Boström, Nordgren, & Haglund, 2009). In the period leading up to the ban, Sweden had a lower overall level of smoking than did Finland, but both were trending down at a remarkably similar rate. This overall trend in the smoking rate highlights the need to include a control that can account for a decline in the smoking rate over time.

The fact that Sweden applied for an exemption while Finland did not suggest that snus was relatively more popular in Sweden than in Finland. Sweden’s response may have been influenced by differing popular and corporate response to the proposed ban. Snus originated in Sweden and there is a long history of use within that country. In addition to the importance of snus in popular culture, it is also an important product commercially. Swedish Match, Sweden’s largest tobacco manufacture, is one of the top 25 largest companies in Sweden. It produces snus and does not manufacture or sell cigarettes. However, it should not be interpreted as an indication that snus was not used in Finland during this time. The ban of snus in Finland has been met with considerable reluctance. For example, Åland, a semi-autonomous island of Finland, agreed to join the EU, but refused to stop selling snus. This has resulted in the assessment of fines and culminated with the island threatening secession from the EU if forced to ban snus (Ben-Aaron, 2008).

Detailed statistics on adult snus consumption in Finland prior to the ban are not available as they were not collected. Finland began including questions pertaining to snus use in their annual health survey in 2000. Results of the survey are not publically available. However, retail tax receipt data, obtained from the ESTOC and available from 1977 to 1994, can proxy for overall country level consumption. Fig. 1 depicts snus consumption (in tons) pre-ban

Fig. 1. Snus sales in Finland (males and females), 1977–1994.

during 1977–1994 in Finland, approximated through tax receipts. Although consumption was relatively stable in the late 1970s and early 1980s, snus use in Finland increased rapidly in the 10 year period leading up to the ban. Between 1980 and 1989, snus consumption doubled in Finland. By 1994, it increased another 30 percent. Data collected in youth tobacco surveys supports the claim that snus was widely used in Finland prior to the ban and can be used to compare the prevalence among Swedish and Finnish youths in the pre-ban period. Using data from youth tobacco use surveys in Finland, [Huhtala, Rainio, and Rimpela \(2006\)](#) find that in 1994, roughly 30 percent of 16 year old males reported that they had tried snus and 6 percent indicated that they were occasional/daily users. [Nilsson, Weinehall, Bergstrom, Stenlund, and Janlert \(2009\)](#) report similar use during the same period in Sweden; 34 percent of 17 year old males reported that they had tried snus and 12 percent indicated that they were occasional/daily users. The adult consumption data and youth usage data taken together suggest that snus was widely available and utilised in Finland prior to the ban.

Because snus use is uncommon outside of Scandinavia, the analysis presented here focuses only on Sweden, Finland, and Norway. Other countries within the European Union were not included in this analysis as it would not be appropriate to do so within this framework. As other countries outside Scandinavia differ in many ways, including the use of snus, tobacco control policies, European Union member status, and trends in the smoking rate both in the period before and after 1995, there is no basis to include them as additional control groups. To explore the effect of limiting access to the less harmful alternative, I restrict my attention to males as snus use among females is far less common. As such, female smoking status is not expected to be impacted by the ban on snus. They would neither have been induced to smoke via access to this less harmful alternative, nor would they have used it as a means to quit smoking.

To investigate the effect of removing snus from the Finnish market, I compare the change in the smoking rate between Finland and Sweden. Within this context, Sweden is the control and Finland is the treatment group. The intervention is joining the EU in 1995. Successful implementation of this type of analysis requires that in the absence of the intervention, the smoking rate in Finland would have looked like that in Sweden. As noted above, both countries are substantially similar which allows Sweden to act as a reasonable control. An alternate specification uses Norway as a control for Finland. However, although snus remains legal in that country, it is considered to be an inferior control as it did not become a member of the EU and would not have experienced the similar societal and economic impacts due to joining.

The data used in this analysis was obtained from the WHO and includes the percent of male smokers in the population per year during the period 1988–2004.

Fig. 2. Male smokers (as a percent of the population) by age group in Finland: 1988–2004.

The regression equation has the following form:

$$Y_{i,t} = \gamma_0 + \gamma_1 \text{Treat}_i + \gamma_2 \text{Post}_t + \gamma_3 \text{Treat}_i * \text{Post}_t + \varepsilon_{i,t}$$

$Y_{i,t}$  is the smoking rate for country  $i$  in year  $t$ .  $\text{Treat}_i$  is a binary variable indicating treatment status, 1 if Finland, 0 if the control (Sweden or Norway),  $\text{Post}_t$  is a binary variable, 1 if the period is after the change (1995–2004), 0 if not (1988–1994), and  $\text{Treat}_i * \text{Post}_t$  is the interaction term.

#### Trend analysis

Although there are many factors which influence smoking prevalence (advertising, smoking cessation campaigns, price, etc.), I undertake a simple analysis to test for a break in trend in the smoking rate in Finland. Using pooled cross sectional data that presents the smoking rate by age group in Finland, I test to see whether there was a structural change in the smoking rate corresponding to implementation of the ban on snus. As snus use was growing rapidly in the pre-1995 period, I focus on only those years immediately preceding the implementation of the ban. During this time, there was a significant reduction in the smoking rate for nearly all age groups as depicted in Fig. 2.

Data on the smoking rate for males is available by age group (age 15–24, 25–34, 35–44, 45–54, and 55–64), which results in a sample size of 85 observations. Disaggregating the rate by age group reveals differences in the change in the smoking rate by age. In order to test whether the rate of change differs between the pre- and post-ban periods, I estimate the following equation:

$$\text{Smoking Rate} = \beta_0 + \beta_1 \text{Year} + \beta_2 \text{Year} + \beta_3 \text{Year} * \text{Post} + \beta_4 \mathbf{X} + \varepsilon,$$

where *Smoking Rate* is the annual smoking rate and *Year* indicates the time period corresponding to that particular rate, with the year normalised so that  $-1 = 1993$ ,  $0 = 1994$ ,  $+1 = 1995$ , etc. *Post* is a binary variable, 1 if the period is after the change (1995–2004), 0 if not.  $\text{Year} * \text{Post}$  is the interaction term.  $\mathbf{X}$  is a vector of dummy variables indicating the age-group for which the smoking rate applies.

Including the interaction term in the above equation allows both the intercept and slope to change between the two periods. In essence, this is akin to computing a Chow Test, where the significance of the coefficient on the interaction term,  $\beta_3$  can be used to test for a structural change across time. If there were no change across time, the variable is expected to be statistically indistinguishable from zero.

Fig. 3. Male smokers (as a percent of the population) in Sweden and Finland, pre and post intervention: 1988–2004.

## Results

Fig. 3 presents the male smoking rate in Finland and Sweden during the period 1988–2004. Prior to the ban, Sweden has a lower level of smoking than does Finland, but both are trending down at a similar rate. Subsequent to the ban on snus in Finland, the rates diverge. The break corresponds to the date of the intervention, 1995.

Norway borders Sweden to the west and has not joined the European Union. Snus is popular in this country, and as in Sweden, is sold legally. Norway does not experience an intervention (as does Finland), and can be used as an alternative, albeit inferior, control. We see in Fig. 4 that the smoking rate in Norway is similar to that in Finland prior to 1995, after which point the rates diverge. Using Norway in place of Sweden as a control produces a result similar to, but not as drastic as, that depicted in Fig. 3.

The rate of change analysis using males in Sweden and Finland is presented in row (1) of Table 1. It shows that in the post-ban period, smoking increased in Finland by 3.47 percentage points relative to Sweden. If Sweden is an appropriate control, then this estimate can be interpreted as an increase in the smoking rate, *relative to what it would have been*, in the absence of the ban. The difference in means is statistically significant at the 5 percent level and can be interpreted as suggestive evidence of a true change due to the treatment.

Note: OLS regression, with the percent of the population that smokes in a given year as the dependent variable. Age variables are indicator functions and are used to indicate smoking rate by age group. The sample is limited to the period 1988–2004 and includes males only. The omitted age group is males age 15–24.

\*  $p < 0.10$ .

\*\* Indicates statistically significant at the 5% level.

\*\*\* Indicates statistically significant at the 1% level.

Fig. 2 illustrates the yearly smoking rate in Finland by age group over this period. Although the rate of change exhibited among males age 45–54 is slight, the smoking rate declines among all age groups in the pre-ban period. Post-ban, the rate of decline slows, and for males at both ends of the age spectrum, it levels out.

Regression results presented in Table 2 indicate there was a shift in the rate across time, with the coefficient positive and statistically significant at the 5 percent level. Note that this analysis implicitly assumes that there has been no other confounding factor that has influenced the rate. To validate this assumption, exploring the smoking behaviour of Finnish females is helpful as they serve as a useful barometer regarding change in price or tobacco control policies during this time which would have influenced the smoking rate in the country. We would expect this group to be wholly unaffected in the change of the policy to ban snus. Finnish females largely did not consume snus, so while removing the product from the market may have affected male consumers, it should have had no bearing on females. In comparing the change in the smoking rate between males and females in Finland, we see in both Fig. 5 and Table 1, row (2) that the rate of change differs significantly by gender. In particular, there was virtually no change in the smoking rate among females during stable during 1988–2004. The findings

Fig. 5. Male and female smokers (as a percent of the population) in Finland, pre and post intervention: 1988–2004.

of this analysis suggest that the adoption of the ban on snus in Finland had a material effect on the smoking rate.

## Discussion

The analysis employed in this research paper utilised aggregate level data on the smoking rate for Scandinavian countries. In comparing the change in the smoking rate between Sweden and Finland, the two countries which joined the EU in 1995, we see that the smoking rate in Finland increased relative to Sweden. We can interpret this to suggest that the smoking rate in Finland is higher than what it would have been in the absence of the ban. As a secondary analysis, I explore the smoking rate of Finnish males and find that there was a structural break in trend corresponding to the date of the ban.

It is possible that the increase in the smoking rate in Finland, relative to Sweden, is due to snus users switching from snus to cigarettes once snus becomes unavailable. If this were the case, it would represent a one-time shock to the smoking rate. However, the data does not support this argument. In the post intervention time period, Finland never again experiences a decline in their smoking rate similar to that experienced pre-ban.

These findings indicate that the ban on snus may be counter-productive. The analysis presented here suggests that snus use is effective in facilitating smoking cessation. These results indicate that limiting the availability of snus, a less harmful alternative to cigarettes, resulted in a reduction in the decline of smoking.

The results of this analysis support findings from surveys suggesting that consumers are willing to substitute snus for cigarettes. However, the degree of substitutability may vary by the individual's characteristics. Lund (2012) finds that the willingness to substitute snus for cigarettes depends upon the individual's perception of the relative risk between the two products. Although Ramström and Foulds (2006) found that the use of snus was similar among individuals with differing levels of age and education when exploring the issue of selection (that smokers who use snus to quit are different than those who use a different aid), there may be other individual characteristics correlated with the probability of uptake. While substitution is considered evidence of a positive incentive, negative effects may exist. The availability of this less harmful alternative can have negative consequences as it may lead to uptake among those individuals who would have otherwise abstained. In addition, those individuals that use snus to quit smoking may continue use long term and remain nicotine dependent. However, both scenarios must be considered in light of the alternative. Smoking is

remarkably more harmful than snus use, and some uptake may be an acceptable consequence of achieving meaningful reductions in the smoking rate, especially when the harm associated with use is relatively low. Gartner et al. (2007) find that in comparing smokers that quit tobacco entirely and those that transitioned to snus, there was little difference in health-adjusted life expectancy. In considering uptake, they report that there would need to be between 14 and 25 non-smokers who take up snus to cancel out the benefit from each smoker who transitions from cigarettes to snus.

The findings presented in this paper provide support for the viability of a harm reduction approach to smoking cessation and suggest that the Swedish Experience could be replicated elsewhere, a perception shared by other researchers such as Ramström (2011). It may have been underway in Finland prior to the implementation of the ban. These results are not only meaningful within Finland, but may be applicable to the entire EU. The smoking rate among Swedish males is remarkable low, and continues to decline; given Sweden's low smoking rate pre-1995, the ability to achieve further reductions post-1995 is notable. To achieve significant reduction in the smoking rate of other member countries in the EU, embracing evidence based policy setting and offering acceptable substitutes is critical.

## Disclosure

This project developed from work I began while at North Carolina State University and was completed while employed at FTI Consulting. The views presented here are my own and do not represent those of either institution. There was no funding provided to support this project.

## Abstract

**Introduction:** Sweeteners in tobacco products may influence use initiation and reinforcement, with special appeal to adolescents. Recent analytical studies of smokeless tobacco products (snuff, snus, dissolvables) detected flavorants identical to those added to confectionary products such as hard candy and chewing gum. However, these studies did not determine the levels of sweeteners. The objective of the present study was to quantify added sweeteners in smokeless tobacco products, a dissolvable product, electronic cigarette liquids and to compare with sweetener levels in confectionary products.

**Methods:** Sweetener content of US-sourced smokeless tobacco, electronic cigarette liquid, and confectionary product samples was analyzed by liquid chromatography-electrospray ionization–mass spectrometry (LC-ESI-MS).

**Results:** All smokeless products contained synthetic high intensity sweeteners, with snus and dissolvables exceeding levels in confectionary products (as much as 25-fold). All snus samples contained sucralose and most also aspartame, but no saccharin. In contrast, all moist snuff samples contained saccharin. The dissolvable sample contained sucralose and sorbitol. Ethyl maltol was the most common sweet-associated component in electronic cigarette liquids.

**Discussion:** Sweetener content was dependent on product category, with saccharin in moist snuff, an older category, sucralose added at high levels to more recently introduced products (snus, dissolvable) and ethyl maltol in electronic cigarette liquid. The very high sweetener concentrations may be necessary for the consumer to tolerate the otherwise aversive flavors of tobacco ingredients. Regulation of sweetener levels in smokeless tobacco products may be an effective measure to modify product attractiveness, initiation and use patterns.

**Implications:** Dissolvables, snus and electronic cigarettes have been promoted as risk-mitigation products due to their relatively low content of nitrosamines and other tobacco toxicants. This study is the first to quantify high intensity sweeteners in snus and dissolvable products. Snus and dissolvables contain the high intensity sweetener, sucralose, at levels higher than in confectionary products. The high sweetness of alternative tobacco products makes these products attractive to adolescents. Regulation of sweetener content in non-cigarette products is suggested as an efficient means to control product palatability and to reduce initiation in adolescents.

## Introduction

In the United States, the Family Smoking Prevention and Tobacco Control Act (FSPTCA) restricts the sales of flavored cigarettes, with the exemption of menthol cigarettes. These restrictions do not apply to smokeless tobacco products, cigars, and electronic cigarettes. These products are available in a wide range of flavors with novel flavor combinations introduced almost daily. The presence of characterizing flavor additives is expected to attract both smokers and non-smokers, and especially adolescents.<sup>1-3</sup> Previous studies have noted similarities in the content of flavor chemicals in tobacco products and confectionary products such as hard candy, mints, and chewing gum.<sup>4,5</sup> Tobacco flavorants include many of the esters, alcohols, terpenes, and aromatic chemicals added to foods. For example, benzyl alcohol is used as a flavoring both in cherry candies and cherry-flavored tobacco products.<sup>5</sup> Electronic cigarette liquids also contain a wide range of known flavor chemicals used in the food industry.<sup>6</sup>

In contrast to these aroma flavorings, only limited information is available about the presence of sweeteners in the currently marketed smokeless tobacco products and electronic cigarette liquids. Traditionally, chewing tobacco and moist snuff have been sweetened either with table sugar (sucrose), causing documented oral health problems in users, or with saccharin.<sup>7,8</sup> Tobacco Industry Documents list sweetener contents in some products, however, this information is likely outdated and new sweeteners and product categories have been introduced.<sup>9,10</sup> For currently marketed products manufacturers list sweeteners as ingredients, including saccharin and sucralose, high intensity sweeteners several hundred times sweeter than sucrose.<sup>10-16</sup> The quantities and types of sweeteners contained in individual products, and how these compare to confectionary products, are unknown.

Sweeteners have powerful psychophysical effects and are known to mask the unpleasant taste of tobacco constituents and reduce oral aversion to nicotine in animals.<sup>17,18</sup> Analogous to candies and sweetened beverages designed to appeal to teenagers and young adults, addition of sweeteners to tobacco products might promote product uptake and determine preference and use patterns.<sup>19,20</sup>

In the present study, 18 tobacco products, including snus, moist snuff, dissolvable tobacco, and electronic cigarette liquids marketed in the United States were analyzed by liquid chromatography–mass spectrometry [LC-MS], to determine levels of natural and high-intensity sweeteners. Sweetener contents in representative confectionary products and soda were analyzed and compared.

## Methods

### Product Samples

Sixteen tobacco products were purchased from stores in the New Haven, CT, area including four snus products, five moist snuffs, five electronic cigarette cartridges, and two electronic cigarette refill liquids. One electronic refill liquid was purchased online from the manufacturer (V2), and one dissolvable tobacco product was procured from an out of state online vendor. For comparison with other high-intensity sweetened products, four sugar-free confectionary products of different brands and two sugar-free beverages of different brands were bought from area stores (Supplementary Table 1).

### Chemical Analysis

Levels of synthetic high-intensity sweeteners (sucralose, cyclamates, saccharin, aspartame, acesulfame potassium), bio-derived

high-intensity sweeteners (stevioside, glycyrrhizin), sugar alcohols, natural sugars, and other constituents were determined by a modified LC-MS method previously used in our laboratory for the analysis of sweetener content in environmental samples<sup>21</sup> (Supplementary Methods). This technique provides a conservative estimate of sweetener levels; in some samples the tobacco matrix may cause minor suppression of MS response.<sup>22</sup>

## Results

All tested products contained no or only very small amounts of the sugars, glucose (<0.072 % w/w) or sucrose (<0.024 % w/w). As expected, the high-intensity sweeteners, sucralose, or aspartame, were detected in the soda and confectionary products (Table 1). The bulk of all mint lozenge products consisted of the sugar alcohol, sorbitol. Sucralose was detected in all snus products at high levels, with three of the four snus products also containing aspartame (Table 1). Saccharin was only detected in the moist snuff products. Snuff products contained no aspartame and only one contained a comparably small amount of sucralose (Skool mint Xtra). No high-intensity sweeteners were detected in the electronic cigarette liquids tested (Table 1). Two of the liquids contained traces of sorbitol (<0.003 % w/w). Ethyl maltol was detected in six of the eight liquids. All the E-liquids had glycerol as carrier, three of them also contained propylene glycol (Supplementary Table 2). The dissolvable product consisted of a large percentage ( $59.0 \pm 3.0$  % w/w) of sorbitol, and contained a high amount of sucralose, but no aspartame or saccharin (Table 1).

The average total amount of sucralose per product unit (piece, lozenge, or strip) was calculated for the sucralose-containing confectionary and smokeless tobacco products (Figure 1). Amounts of sucralose per unit were much higher in the snus products (>6 mg/unit, one product > 11 mg/unit) than in the confectionary products (<0.4 mg/unit). The single snuff product containing sucralose had <1 mg/unit. Sucralose content in the dissolvable product was higher (4.48 mg/unit).

Among the nine snus and moist snuff products, seven were in the form of small pouches. The content of sweeteners in the pouch material, comprising about 10% of total product weight, followed distributions in the bulk products, but concentrations were all lower (Supplementary Tables 3–5).

## Discussion

In the present study, all the tested snus and moist snuff products contained high-intensity sweeteners. All tested moist snuff products contained saccharin as the sole added synthetic sweetener with one exception containing roughly equal amounts of both saccharin and sucralose. Manufacturers have been adding saccharin to smokeless tobacco products since 1891, when R. J. Reynolds introduced saccharin-sweetened chewing tobacco.<sup>7</sup> In fact, the tobacco industry was the first to license synthetic high-intensity sweeteners to add to consumer products, likely to improve shelf stability, product uniformity and create brand identity.<sup>7</sup> The majority of the moist snuff products investigated here were brought to market prior to introduction of sucralose in 1999.<sup>10</sup> Saccharin, in addition to being perceived as sweet, has a bitter taste, a property not shared by sucralose and aspartame that have replaced saccharin in most high-intensity sweetened food products.<sup>3</sup> It is possible that tobacco manufacturers did not replace saccharin in snuff products because long term users have

Data are stated as % w/w of product unit as received; means from three samples each, with standard error; blank fields indicate nondetected (n.d.)

**Figure 1.** Comparison of sucralose content in product units of confectionary products and snus. Average content of sucralose in mg per piece or pouch is displayed. Data derived from Table 1.

been habituated to its taste profile and would disapprove of a change to other sweeteners. This view is also supported by the observation that saccharin content in the currently marketed products analyzed here did not differ much from levels determined in snuff products more than 20 years ago.<sup>9</sup> The lower price of saccharin compared to sucralose may also explain its continued use in the product category.

In contrast, all four snus products tested here contained sucralose, most in combination with aspartame. Snus products were introduced to the US market in 2006 when sucralose was already widely used in food products.<sup>23</sup> Sucralose content in the tested snus products, both % w/w and weight per product unit, exceeded the levels in any of the other solid confectionary products (candy, mint lozenges, chewing gum). The absolute amounts of sucralose in snus were 14- to 25-fold higher than the highest content found in a candy product. The bulk of some of the confectionary products consisted of a high percentage of sorbitol, a sugar alcohol with a sweetness lower than table sugar (sucrose). Together with sorbitol, smaller amounts of sucralose and aspartame are likely sufficient for these products to reach the desired level of sweetness. Intriguingly, the dissolvable tobacco product tested here also contained substantial amounts of sorbitol with sucralose added at an amount approaching that found in the snus products.

Six of the eight E-cigarette liquids contained ethyl maltol, known to be a sweet taste potentiator and previously reported in E-liquids.<sup>5,6,24</sup> Propylene glycol and glycerol, the major constituents of the E-liquids tested, are lightly sweet. Their sweetness may be enhanced by ethyl maltol and other popular sweet-associated flavorings.<sup>25,26</sup> Ethyl maltol was awarded GRAS status (Generally Recognized As Safe) from the Flavor & Extracts Manufacturers Association (FEMA) for the intended use as a food additive. Some E-liquids vendors advertise the GRAS label as supportive of safety for the flavorants added to their products. However, FEMA has repudiated these claims since GRAS status only applies to use in food and not in E-cigarettes for inhalational delivery.<sup>27</sup> It is unknown whether ethyl maltol is chemically stable in E-liquids, and when these are heated and vaporized.

High-intensity sweeteners were not detected in the E-liquids tested suggesting that the major manufacturers of E-cigarettes and -liquids do not include high-intensity sweeteners in their E-liquid formulations. However, online vendors currently offer sucralose liquids for sale to customers to mix with their E-liquids. While sucralose is an FDA-approved food additive, its health effects and metabolic fate when delivered by E-cigarette are unknown.

In summary, the current findings suggest that US-marketed new smokeless tobacco products, snus and dissolvables, are more highly sweetened than confectionary products. With sucralose perceived as 600 times sweeter than sugar, and added aspartame, the sweetness of snus and dissolvable products exceed the sweetness of their unit (pouch or lozenge) weight in sugar. Optimal sweetener levels were likely determined in tests by company-internal panelists and consumer groups, suggesting that higher levels of sweetness are required to establish palatability and liking of these tobacco-containing products. The intense sweetness may be necessary to mask the adverse taste and sensory effects of the processed tobacco that contains irritating and bitter nicotine and other tobacco constituents with adverse tastes. Sweeteners are known to suppress the perception of bitter taste and to inhibit the sensation of irritation.<sup>28</sup> While sucralose uptake from snus alone is unlikely to exceed the FDA-determined acceptable daily intake (ADI), daily repeated use of snus together with consumption of other sucralose-sweetened products such as soda, sweetener packets and food products may lead to continuous high exposure. Recent studies revealed that high-intensity sweeteners affected metabolic signaling in pancreatic beta cells and changed the composition of the gut microbiome, potentially contributing to metabolic dysregulation.<sup>29</sup>

Dissolvables and snus have been promoted as risk-mitigation products due to their relatively low content of nitrosamines and other tobacco toxicants. While not as popular, these products may increase the risk of polytobacco use and their intense sweetness is of concern since it may appeal especially to adolescents who initiate tobacco product use.<sup>30,31</sup> In addition to E-cigarettes, other sweet flavored tobacco products such as small cigars have made rapid inroads among adolescent populations and remain unregulated.<sup>32,33</sup> Among the wide variety of flavors offered intense sweetness appears to be a common denominator in the majority of the newly introduced products. Thus, the regulation of sweetener content may represent an efficient means to control palatability of a wide range of products and to reduce tobacco product use initiation.

## ABSTRACT

**Background:** Recent studies suggest a possible causal role for smoking in schizophrenia and psychosis. Most studies have focused on cigarette smoking, the most common form of tobacco use, but other forms of tobacco exist, including smokeless products such as Swedish snuff (or “snus”).

**Methods:** We explored whether snus use is associated with schizophrenia and non-affective psychotic illness in a large Swedish registry data set. The majority of participants were aged 18 or 19 at the time of assessment.

**Results:** We observed a positive association between snus use and odds of schizophrenia in all analyses, but the magnitude of the association was small and the confidence interval wide, consistent with no association (fully adjusted HR 1.03, 95% CI 0.70–1.54). A similar pattern was observed for non-affective psychosis, but the magnitude of the association was somewhat greater and the confidence intervals narrower, so that these analyses provided stronger statistical evidence for this association (fully adjusted HR 1.22, 95% CI, 1.00–1.48).

**Conclusions:** Our results therefore provide modest evidence for an association between snus use and risk for non-affective psychosis. This is consistent with emerging evidence from a range of studies and methodologies that tobacco use may be a risk factor for psychotic illness. However, our results provide some evidence against the hypothesis that it is the burnt products of cigarette smoke that are psychotogenic.

## 1. Introduction

Tobacco use prevalence is considerably higher among psychiatric patients, including people with schizophrenia, compared with the general population (de Leon and Diaz, 2005). For the most part, it has been assumed that this comorbidity reflects, at least in part, self-medication on the part of individuals with schizophrenia, to remediate either the symptoms of the disease, or the side-effects of antipsychotic medication. The possibility that the association may reflect a causal effect of tobacco use on schizophrenia risk has not received widespread consideration, despite the fact that tobacco use typically predates the onset of psychotic symptoms.

If smoking is indeed a causal risk factor for schizophrenia, then this has important implications for public health, prevention and treatment.

A recent genome-wide association study of schizophrenia (Schizophrenia-Working-Group-of-the-Psychiatric-Genomics-Consortium, 2014) identified a locus in the *CHRNA5-A3-B4* gene cluster on chromosome 15, which has been consistently shown to be associated with heaviness of smoking (Tobacco-and-Genetics-Consortium, 2010). One possible explanation for this finding is that this signal captures a causal effect of cigarette smoking on schizophrenia (Gage and Munafò, 2015). There is a precedent for this pattern of results: the same region was shown to be associated with lung cancer risk (Thorgerirsson et al., 2008) but it is likely that this effect arises entirely via cigarette smoking (Munafò et al., 2012).

Intriguingly, several other recent studies have been published which also support a causal role for smoking in schizophrenia and psychosis (Gurillo et al., 2015; Kendler et al., 2015; McGrath et al.,

2015; Wium-Andersen et al., 2015). One study reported a stratified analysis which suggests an association of *CHRNA5-A3-B4* genotype with antipsychotic medication prescription (as a proxy of psychotic illness) in ever smokers but not in never smokers (Wium-Andersen et al., 2015). Another used Swedish registry data to show that cigarette smoking predicted subsequent diagnosis of schizophrenia, and this association was not substantially altered either by potential confounders either using standard regression methods or co-relative analyses, or by the inclusion of a buffer period to account for the possibility that prodromal symptoms of schizophrenia prior to a diagnosis might lead to the uptake of smoking (Munafò et al., 2012).

Most studies to date have focused on cigarette smoking, largely because this is by far the most common form of tobacco use. However, other forms of tobacco use exist, such as smokeless forms including oral preparation such as Swedish snuff (or “snus”). Snus is a moist powder tobacco product, typically sold in prepackaged pouches and usually placed under the upper lip. In general, snus use is associated with lower levels of harm than cigarette smoking (Le Houezec et al., 2011), although the evidence with respect to psychiatric outcomes is limited. We therefore explored whether a similar pattern of association is seen between snus use and schizophrenia and non-affective psychotic illness in a large Swedish registry data set. There is clear evidence that schizophrenia lies at the end of a continuum of vulnerability to psychotic-like symptoms and psychosis. Including non-affective psychosis therefore allowed us to increase statistical power while still addressing our underlying question.

## 2. Methods

### 2.1. Participants

We linked nationwide Swedish registers via the unique 10-digit identification number assigned at birth or immigration to all Swedish residents. The identification number was replaced by a serial number to ensure anonymity. Our database contained the following sources: the Multi-Generation Register, the Swedish Hospital Discharge Register, the Swedish Prescribed Drug Register, the Outpatient Care Register, the Primary Health Care Register, the Swedish Crime Register, the Swedish Suspicion Register, the Military Conscription Register, the Population and Housing Censuses, and the Total Population Register. More information on these data sources is provided as Supplementary material. Males with valid snus and smoking assessments, aged 18–25 at the time of conscription were eligible for inclusion. During the period sampled, all Swedish males were required by law to attend two days of evaluation for conscription. Only individuals with prior disabilities or serious criminal or behavioral disturbances were exempted. Around 97% of males are included in this sample. End of follow-up was the last year of information available, which for most registries was 2010.

### 2.2. Measures

We identified smoking and snus habits in young males from the Military Conscription Register. Snus use was assessed as “Yes” or “No”, while smoking was assessed as follows: (1) “Not smoking”, (2) Light smoking—(Winkleby et al., 2007) “1–10 cigarettes/day”, or “1 packet of tobacco/week”, (3) Average smoking—“11–20 cigarettes/day”, or “1–2 packets/week”, and (4) heavy smoking—“>20 cigarettes/day”, or “>2 packets/week.” Schizophrenia (SZ) was defined in the Swedish Hospital Discharge Register by the following ICD 10 codes: F20.0, F20.1, F20.2, F20.3, F20.5, F20.8, and F20.9. Non-affective psychosis (NAP) was defined

by the ICD 10 code: F2. More information on these codes is provided as Supplementary material.

Drug abuse (DA) was defined as follows: in the Swedish medical registries by ICD 10 codes: F10–F19, except (F10) or (F17); in the Suspicion Register by codes 3070, 5010, 5011, and 5012, that reflect crimes related to DA; and in the Crime Register by references to laws covering narcotics (law 1968:64, paragraph 1, point 6) and drug-related driving offences (law 1951:649, paragraph 4, subsection 2 and paragraph 4A, subsection 2). DA was identified in individuals (excluding those suffering from cancer) in the Prescribed Drug Register who had retrieved (in average) more than four defined daily doses a day for 12 months from either of Hypnotics and Sedatives (Anatomical Therapeutic Chemical (ATC) Classification System N05C and N05BA) or Opioids (ATC: N02A). These levels were set to be beyond what any responsible physician in Sweden would prescribe for anxiety or pain and would only arise from someone who is abusing the medications, often through getting multiple prescriptions from different physicians. This method of drug abuse assessment is validated by the strong correlation in probability of registration for drug abuse from medical and crime registries.

Family level socioeconomic status was assessed by low parental education, defined as elementary school only to index low educational attainment. Neighborhood level socioeconomic status was assessed by a composite measure of neighbourhood deprivation (Winkleby et al., 2007), which has been validated in prior studies (Chaikiat et al., 2012; Winkleby et al., 2007). In the year of conscription, this measure was classified into low, mid and high. This approach avoids problems associated with classifying socioeconomic status at the individual level, which may be impacted by current and recent behavior (e.g. drug use).

### 2.3. Statistical analysis

We investigated the association between snus and time to diagnosis in males not diagnosed with non-affective psychosis (including schizophrenia) before conscription with Cox proportional hazard methods, censoring at death or end of follow-up. The association between smoking and schizophrenia/non-affective psychosis is known and we therefore included the smoking  $\times$  snus interaction in the model.

In addition to unadjusted analyses we adjusted for socioeconomic status, assessed as parental education at the individual level and neighbourhood deprivation, and DA before SZ/NAP onset. To facilitate interpretation, we present the snus associations separately by smoking category. Statistical analyses were performed using SAS 9.3 (18).

## 3. Results

### 3.1. Characteristics of participants

Of the 227,117 individuals fulfilling the inclusion criteria, 60,804 (26.8%) reported being snus users. The vast majority of participants ( $N = 223,412$ , 98.4%) were aged 18 or 19 at the time of assessment. A full description of the characteristics of participants, including snus users and non-users, is provided in Table 1.

### 3.2. Association of snus use with schizophrenia and non-affective psychosis

There was a positive association between snus use and odds of schizophrenia in all analyses, but the magnitude of the associations were small and the confidence intervals wide (unadjusted HR 1.13, 95% CI 0.77–1.67; partially adjusted HR 1.14, 95% CI 0.77–1.68; fully adjusted HR 1.03, 95% CI 0.70–1.54) (Table 2). However, the small

**Table 1**  
Characteristics of participants.

	All N = 227,117	Not using snus N = 166,313	Using snus N = 60,804

**Table 2**  
Association of snus use with schizophrenia/non-affective psychosis, by smoking status.

	Unadjusted	Partially adjusted <sup>a</sup>	Fully adjusted <sup>b</sup>
Schizophrenia			
Combined	1.13 (0.77, 1.67)	1.14 (0.77, 1.68)	1.03 (0.70, 1.54)
Non-smoker	1.29 (0.81, 2.08)	1.30 (0.81, 2.08)	1.23 (0.77, 1.98)
Light smoker	0.38 (0.15, 0.97)	1.39 (0.15, 1.01)	0.42 (0.16, 1.07)
Moderate smoker	0.67 (0.17, 2.57)	0.69 (0.18, 2.70)	0.75 (0.19, 2.92)
Heavy smoker	1.22 (0.25, 6.04)	1.26 (0.26, 6.22)	1.43 (0.29, 2.08)
Non-affective psychosis			
Combined	1.33 (1.10, 1.61)	1.33 (1.09, 1.61)	1.22 (1.00, 1.48)
Non-smoker	1.44 (1.14, 1.82)	1.45 (1.15, 1.83)	1.38 (1.09, 1.75)
Light smoker	0.65 (0.43, 0.99)	0.66 (0.43, 1.00)	0.69 (0.45, 1.05)
Moderate smoker	0.87 (0.45, 1.67)	0.90 (0.47, 1.74)	0.97 (0.50, 1.87)
Heavy smoker	0.54 (0.17, 1.75)	0.56 (0.17, 1.81)	0.63 (0.19, 2.06)

Values represent hazard ratios (95% confidence interval). Light smoking is defined as 1–10 cigarettes/day, or 1 packet of tobacco/week, moderate smoking as 11–20 cigarettes/day, or 1–2 packets/week, and heavy smoking as >20 cigarettes/day, or >2 packets/week. Analyses in combined sample are adjusted for smoking status.

<sup>a</sup> Additionally adjusted for neighbourhood deprivation, parental education.

<sup>b</sup> Additionally adjusted for drug abuse prior to diagnosis.

number of schizophrenia cases in these analyses meant that statistical power was low.

A similar pattern was observed for non-affective psychosis (including schizophrenia), but the magnitude of the association was somewhat greater and the confidence intervals narrower. These analyses provided statistical evidence that this association was unlikely due to chance effects (unadjusted HR 1.33, 95% CI 1.10–1.61; partially adjusted HR 1.33, 95% CI 1.09–1.61; fully adjusted HR 1.22, 95% CI, 1.00–1.48) (Table 2).

### 3.3. Association by smoking status

We examined the relationship between snus use and risk for schizophrenia and non-affective psychosis separately by cigarette smoking status (Table 2). Evidence for an association was only reliably seen in non-smokers where, for non-affective psychosis, the HR was approximately 1.4 and changed little with adjustment.

## 4. Discussion

Our results provide modest evidence for an association between snus use and risk for non-affective psychosis. Although a broadly similar pattern of results was observed for snus use and schizophrenia, our analysis was underpowered for this outcome, making it difficult to draw any conclusions with confidence. When we considered snus use separately in non-smokers and smokers we observed similar evidence for an association with non-affective psychosis but only in non-smokers, and not in smokers. While the magnitude of the associations we observed was modest, for a common exposure such as tobacco use the population level impact of any causal effect will nevertheless be substantial.

It is notable that the association between snus use and risk for non-affective psychosis was only observed in non-smokers. This may be because, among smokers who also use snus, cigarettes represent the major source of tobacco exposure. However, we also observed evidence among smokers of a modest negative correlation between snus use and cigarette use. This may reflect partial nicotine substitution among dual users, where snus use leads to a corresponding reduction in cigarette smoking, given that tobacco users typically titrate intake to achieve the desired nicotine level. Dissecting the relative contribution of snus and cigarette exposure among dual users is therefore likely to be complex. Taken together, these results provide some evidence against the hypothesis that it is the burnt products of cigarette smoke that are psychotogenic.

There are some limitations that should be considered when interpreting these results. First, despite the relatively large sample size, our study was most likely underpowered to detect modest associations between snus use and a rare outcome such as schizophrenia. However, the overall pattern of results was broadly similar for both outcomes, which increases confidence somewhat in these findings. Second, as with any observational analysis, we cannot fully exclude the possibility that residual confounding or reverse causality may account for the associations we observed. However, the current results are consistent with emerging evidence from a range of studies and methodologies that tobacco use may be a risk factor for psychotic illness. Third, the sample included only conscripted males, and was predominantly of European ancestry, so that the findings are not necessarily generalizable to other populations. It is worth noting that attending the conscript evaluation is mandatory for males in Sweden, so that the sample should be representative of the male Swedish population over the period sampled.

In conclusion, our data provide some evidence that snus use is associated with the subsequent development of non-affective psychosis. The evidence for an association with schizophrenia is weaker, but broadly consistent. Given growing evidence that tobacco use may play a role in the aetiology of psychotic illness, these results are potentially important in that they suggest that any causal agent is present in unburned tobacco. One candidate agent is nicotine, which influences dopaminergic signaling in several brain regions (Subramaniam and Dani, 2015). However, there are other constituents of tobacco that are also plausible candidates, such as monoamine oxidase inhibitors (Hogg, 2015). If tobacco use is in fact a risk factor for psychotic illness, it will be important to identify the constituents responsible, in particular given growing interest in the use of nicotine-containing products (e.g., electronic cigarettes) for harm reduction, including among psychiatric patients.

### What's new?

- The risk of Type 2 diabetes and latent autoimmune diabetes of adulthood (LADA) is not significantly affected by the use of snus, despite its high nicotine content.
- These results raise the possibility that the excess risk of Type 2 diabetes seen in smokers is due to components of tobacco smoke other than nicotine.

### Abstract

**Aims** It has been suggested that moist snuff (snus), a smokeless tobacco product that is high in nicotine and widespread in Scandinavia, increases the risk of Type 2 diabetes. Previous studies are however few, contradictory and, with regard to autoimmune diabetes, lacking. Our aim was to study the association between snus use and the risk of Type 2 diabetes and latent autoimmune diabetes of adulthood (LADA).

**Method** Analyses were based on incident cases (Type 2 diabetes,  $n = 724$ ; LADA,  $n = 200$ ) and population-based controls ( $n = 699$ ) from a Swedish case-control study. Additional analyses were performed on cross-sectional data from the Norwegian HUNT study ( $n = 21\,473$ ) with 829 prevalent cases of Type 2 diabetes. Odds ratios (OR) were estimated adjusted for age, BMI family history of diabetes and smoking. Only men were included.

**Results** No association between snus use and Type 2 diabetes or LADA was seen in the Swedish data. For Type 2 diabetes, the OR for  $> 10$  box-years was 1.00 [95% confidence interval (CI), 0.47 to 2.11] and for LADA 1.01 (95% CI, 0.45 to 2.29). Similarly, in HUNT, the

OR for Type 2 diabetes in ever-users was estimated at 0.91 (95% CI, 0.75 to 1.10) and in heavy users at 0.92 (95% CI, 0.46 to 1.83).

**Conclusion** The risk of Type 2 diabetes and LADA is unrelated to the use of snus, despite its high nicotine content. This opens the possibility of the increased risk of Type 2 diabetes seen in smokers may not be attributed to nicotine, but to other substances in tobacco smoke.

## Introduction

Cigarette smoking is a known risk factor for Type 2 diabetes [1] and is associated with impaired insulin sensitivity [2], proposedly linked to exposure to nicotine [2]. Swedish moist snuff (snus) is a smokeless tobacco product traditionally used most frequently by men; the prevalence of snus use among women is low [3]. Users place a portion or sachet of snus between the gum and upper lip [4]. The nicotine content of snus is higher than that of cigarettes [5]; it may consequently also promote Type 2 diabetes. Few studies have addressed this question and the results are inconclusive [6–8]. Smoking is common among snus users, and one reason for the conflicting results may be insufficient adjustment for smoking. One way to handle this confounding factor is to restrict the analyses to those who have never smoked. However, studies conducted to date have been too small to allow for such analyses. Also, previous studies have not had the power to analyse the impact of different degrees of snus use on Type 2 diabetes.

Nicotine is known to have anti-inflammatory [9] and immune-modulating [10,11] effects, which, theoretically, might increase or decrease the risk of autoimmune diabetes. In a previous study, smokers displayed a reduced risk of latent autoimmune diabetes of adulthood (LADA) [12]. It could be hypothesized that snus with its higher nicotine content may have a stronger

protective effect than smoking. In line with that notion, snus has been linked to a reduced risk of multiple sclerosis, which is also an autoimmune disease [13]. Whether snus use indeed reduces the risk of autoimmune diabetes remains to be investigated.

The aim of this study was to clarify the role of snus use in the development of Type 2 diabetes and LADA, taking into account dose and duration of use, and co-exposure to smoking. These clarifications are important because 20% of men in Sweden use snus on a daily basis [14] and its use is steadily on the rise in Norway and the USA [15].

## Methods

### ESTRID study

This study was based on data from the epidemiological study of risk factors for LADA and Type 2 diabetes (ESTRID) [16]. ESTRID is a sub-study of All New Diabetes in Scania (ANDIS; <http://andis.ludc.med.lu.se>). ANDIS is a large-scale study with the aim of registering all new cases of diabetes in the region of Scania (Southern Sweden; ~ 1 300 000 inhabitants) to improve the classification of diabetes into subgroups on the basis of genetic and phenotypic information. All people with new-onset LADA recorded in ANDIS since 2010, together with a random sample of people with Type 2 diabetes (four per LADA case), were invited to participate in the ESTRID. Controls aged  $\geq 35$  years were randomly selected from the population of Scania without diabetes. Six controls were selected per LADA case, corresponding to one control per case of diabetes (LADA or Type 2). ESTRID is a density-sampled case-control study [17]; it included incident cases and controls that were matched according to participation date and residential area [17]. In 2012, ESTRID expanded the recruitment to All New Diabetes in Uppsala (ANDIU; <http://www.andiu.se/>), a sister study to

ANDIS conducted in the County of Uppsala (middle of Sweden; ~ 300 000 inhabitants) (Fig. S1).

This study is based on cases and controls collected until July 2015, with a participation rate of 81% (cases) and 66% (controls). The analysis was restricted to men because snus use is very rare in women (4.3% of female participants). Those eligible for the current investigation were thus all men with complete data on snus use and covariates of interest, including 200 LADA cases, 724 Type 2 diabetes cases and 699 controls. Of the participants, 97% came from Scania and 3% from Uppsala. Each participant provided informed consent and ethical approval was obtained from ethical review board in Stockholm.

### **Tobacco habits and covariates**

Participants in ESTRID filled out an extensive questionnaire covering lifestyle, health and sociodemographic factors. People with diabetes received questionnaires as close as possible to the time of diagnosis. Questions regarding lifetime use of snus included number of snus boxes consumed per week (each containing 25–50 g), separate for every period, and we used this to calculate the duration of snus use. One box-year was defined as consuming one box of snus per day for one year (calculated in ever-snus users). In addition, intensity of snus use was assessed in two categories in ever-snus users (light, < 5 boxes/week; and heavy,  $\geq$  5 boxes/week).

Information on smoking was obtained in a similar fashion. The cumulative dose of smoking (pack-year) was assessed in ever-smokers. One pack-year was regarded as smoking 20 cigarettes per day for one year. We defined an index date for each case as the year of diagnosis, and for each control as the year of participation. The exposure to different forms of tobacco was assessed for the period prior to the index year.

## Classification of people with diabetes

All people diagnosed with diabetes within the healthcare system of each county provided blood samples for serological analyses upon diagnosis. Glutamic acid decarboxylase antibodies (GAD antibodies) were measured by enzyme-linked immunosorbent assay (RSR Ltd). The cut-off for positivity was 10 IU/ml [18]. At a cut-off level of 10.7 IU/ml, the sensitivity was 84% and the specificity was 98% [18]. C-Peptide status was analysed by IMMULITE 2000 (Siemens Healthcare Diagnostics Product Ltd, Llanberis, UK) or by Cobas e 601 analyser (Roche Diagnostics, Mannheim, Germany) [19]. People with diabetes with age-at-onset  $\geq 35$  years were classified as having LADA if they were GAD antibody positive ( $\geq 10$  IU/ml) with C-peptide  $\geq 0.2$  nmol/l (IMMULITE)/or  $\geq 0.3$  nmol/l (Cobas e 601), and as Type 2 diabetes cases if they were GAD antibody negative ( $< 10$  IU/ml) with C-peptide  $\geq 0.6$  nmol/l (IMMULITE)/or  $\geq 0.72$  nmol/l (Cobas e 601). This is in line with generally used criteria for defining LADA [20], except for C-peptide levels, which were used as an indicator of preserved insulin secretion. Fasting plasma glucose and C-peptide measurements were used to calculate the parameters homeostasis model assessment of insulin resistance (HOMA-IR) to estimate insulin resistance and HOMA-%B to assess  $\beta$ -cell function [21].

## Norwegian HUNT study

HUNT is a large population-based study which consists of three consecutive health surveys conducted between 1984 and 2008 in the Nord-Trøndelag County in Norway [22]. Information on snus use was available for the HUNT3 survey, performed between 2006 and 2008. All inhabitants aged  $\geq 20$  years were invited to participate in the HUNT3 survey. The attendance rate was 54% ( $n = 50\,839$ ). We restricted the analyses to men ( $n = 21\,473$ ) because of the low prevalence of snus use among women (4.4%). People with Type 2 diabetes were diagnosed at

$\geq 35$  years and were GAD antibody negative ( $< 0.08$  antibody index;  $n = 829$ ). GAD antibody positivity was used to identify adult-onset autoimmune diabetes ( $n = 41$ ; including people with LADA and Type 1 diabetes with adult onset), but as the number of affected individuals who used snus was so small ( $n = 10$ ), these persons were omitted from further analyses.

Information on snus use and other lifestyle factors was collected by questionnaire. Participants were asked whether they had ever used snus (on a daily basis/occasionally) and if so, the number of boxes consumed per month. 'Ever' consumers were classified as light ( $< 3$  boxes/week) and heavy ( $\geq 3$  boxes/week) users. The HUNT surveys were conducted according to regulations from the Norwegian Data Inspectorate and the Regional Committee for Medical Research Ethics, including informed consent from participants.

### Statistical methods

Conditional logistic regression (matched for participation date and residential) was used to analyse ESTRID data to estimate the association between snus use and Type 2 diabetes and LADA in terms of the odds ratio (OR) and its 95% confidence interval (CI) (SAS 9.4; SAS Institute, Cary, NC, USA). OR values were interpreted as incidence rate ratios because this case-control study included incident cases and controls sampled by incidence density sampling method (i.e. controls are sampled from the risk set each time a case is diagnosed) [17]. Cross-sectional data was used to calculate ORs by logistic regression models. All analyses were adjusted for age (years, continuous), BMI (calculated as  $\text{kg/m}^2$ , continuous), family history of diabetes (yes/no) and smoking (pack-year, continuous), unless otherwise stated. Further adjustment for educational level, alcohol consumption and physical activity did not alter the results (change in OR  $< 10\%$ ).

## Results

### General characteristics of the study populations

In ESTRID, mean age was 63 years in people with Type 2 diabetes, 57 years in people with LADA and 58 years in controls (Table 1). Compared with people with LADA, those with Type 2 diabetes were older and heavier, and had higher prevalence of a family history of diabetes and lower educational level. People with LADA were less insulin resistant, had lower levels of HOMA- $\beta$  and were more likely to be insulin treated (44% of LADA vs. 6% of Type 2 diabetes). The median duration of diabetes was 5.4 months in people with Type 2 diabetes and 8.0 months in the group with LADA.

Compared with ESTRID participants, those taking part in HUNT were slightly older and leaner, and had lower prevalence of smoking (Table 2). The prevalence of ever-snus use in HUNT (28%) was as common as in ESTRID (30%).

Comparing the characteristics of participants by tobacco use shows that snus users were younger, less likely to have a low level of education, more physically active, and less likely to be alcohol abstainers compared with smokers and those who do not use tobacco (Table S1). The findings were similar in HUNT and ESTRID, and no other clear differences were seen between the groups.

### Snus use and Type 2 diabetes

No association was observed between snus use and Type 2 diabetes in ESTRID (OR, 0.96; 95% CI, 0.67 to 1.37) (Table 3) or in HUNT (OR, 0.91; 95% CI, 0.75 to 1.10) (Table 4). In never-smokers, high snus consumption (ever-users) was not associated with Type 2 diabetes in

either ESTRID (Table 3) [OR, 1.01; 95% CI, 0.42 to 2.41 ( $\geq 5$  box/week)] or HUNT [OR, 0.89; 95% CI, 0.21 to 3.78 ( $\geq 3$  boxes/week)] (Table 4). Additional adjustment for educational level, alcohol consumption and physical activity did not change the results [OR, 1.02; 95% CI, 0.46 to 2.26 ( $\geq 10$  box/year) in ESTRID]. Raising the cut-off in ESTRID to  $\geq 7$  boxes/week indicates an OR of 1.23 (95% CI, 0.34 to 4.47) in ever-users, the results were similar in current heavy snus users (OR, 1.23; 95% CI, 0.30 to 5.12).

### **Snus use and LADA**

In ESTRID, there was no indication of an excess risk of LADA in snus users, but the confidence limits were wide. In never-smokers, OR was estimated at 0.67 (95% CI, 0.24 to 1.86) for  $\geq 5$  box/week and at 1.01 (95% CI, 0.45 to 2.29) for  $\geq 10$  box-year (Table 5).

### **Co-exposure to smoking and snus use**

Combining exposure from snus use and cigarettes showed that only smoking was associated with the risk of diabetes (Tables S2 and S3). In ESTRID, those who only smoke cigarettes ('ever') had increased risk (OR, 1.59; 95% CI, 1.16 to 2.18) of Type 2 diabetes (the details are reported elsewhere [23]), a risk that was even more pronounced in heavy smokers (OR, 2.20; 95% CI, 1.40 to 3.45); whereas no increased risk was seen in those who use only snus, or in those who combine snus use and smoking (Table S2). Similar findings were seen in HUNT; in those who only smoke, the OR for Type 2 diabetes was 1.63 (95% CI, 1.36 to 1.96) (Table S3). As for Type 2 diabetes, any combination of tobacco use was unrelated to the risk of LADA, the OR of LADA for individuals combining snus and cigarettes consumption was estimated at 0.97 (95% CI, 0.62 to 1.52) (Table S2).

## Discussion

The main finding of this study is the lack of an association between snus use and Type 2 diabetes and LADA, this being in contrast to the effects of smoking documented here and previously [1]. For Type 2 diabetes, our negative findings regarding snus use agree with observations from the MONICA study from Northern Sweden [8], but are in contrast to one cross-sectional [6] and one prospective study [7] based on the Stockholm Diabetes Prevention Program. Confounding from smoking may have contributed to conflicting results. Notably, we did see indications of an increased risk of diabetes in snus users, which disappeared when the analysis was restricted to those who had never smoked. In previous studies, small numbers hampered the analyses of snus users who had never smoked; none of those studies included more than six cases [6–8]. In this context, it is worthy of note that there are no data on the risk of diabetes in relation to the use of other forms of smokeless tobacco such as chewing tobacco. However, US data indicate that use of smokeless tobacco (chewing tobacco) is unrelated to mortality in people with diabetes [24].

We confirm epidemiological and experimental studies linking smoking to an increased risk of Type 2 diabetes [1], proposedly mediated by mechanisms including insulin resistance [2]. Why smoking, but not snus use associates with risk of diabetes is not clear, but this fits with previous findings in cardiovascular diseases such as stroke and myocardial infarction [25–27], indicating that the risk induced by smoking by far exceeds that related to snus use. A lesser degree of toxicity may be due to lower levels of many toxins, e.g. nitrosamine in snus than in cigarettes [28]. In this context, it should be noted that pipe smoking, which provides an exposure to nicotine that is fairly similar to cigarette smoking, is associated with a lower risk of heart disease than cigarette smoking [29], suggesting that substances in cigarette smoke other than nicotine might be important for the risk of Type 2 diabetes.

We previously found a reduced risk of LADA in smokers [12] and based on this we hypothesized that snus may be associated with an even more pronounced risk reduction, due to its high nicotine content. By contrast, data from ESTRID indicate that snus use is unrelated to the risk of LADA and furthermore, that heavy smoking may increase the risk [23]. These findings are compatible with both negative and beneficial effects of nicotine on the pathogenesis of LADA and the lack of association with overall risk may reflect that a potential beneficial effect on autoimmunity is counterbalanced by increased insulin resistance. However, with regard to other autoimmune diseases such as rheumatoid arthritis [30] and Crohn's disease [31], for which insulin resistance is not part of the pathogenesis, similar null results have been reported in relation to snus use.

One of the strengths of this study is that it was population-based using incident cases that were identified in large well-characterized diabetes registries (ANDIS/ANDIU) with randomly selected population controls. The number of cases was relatively large and we had detailed information on the history of tobacco use and a large number of potential confounders. Recall bias is a potential problem because both studies were based on retrospective data of tobacco use. ESTRID is based on incident cases, which minimizes this problem; furthermore, only information from the years prior to diagnosis was included in our analysis. The HUNT data were based on prevalent cases and hence, recall bias may be more pronounced, e.g. people with diabetes may have quit using tobacco several years ago following diagnosis, thereby underestimating previous use. Importantly, the association between smoking and Type 2 diabetes in both HUNT and ESTRID was similar to reports from prospective studies with tobacco habits assessed several years prior to onset [1,12]. Furthermore, by restricting a major part of our analyses to never-smokers, we avoid bias that may arise from people shifting from smoking to snus use or vice versa following diagnosis. This is the most extensive analysis conducted to date on the risk of Type 2 diabetes in relation to snus use. As a consequence, we

could perform separate analysis in never-smokers, thereby minimizing confounding from smoking. However, we cannot exclude the possibility that snus use has a small effect on the risk of diabetes, which we did not have enough power to detect. With our current sample size and snus use prevalence (30%), we have 85% power to detect an OR of 1.5 (or 0.65) for Type 2 diabetes. Further, the number of heavy snus users was limited and thus we cannot exclude an effect in the highest consumption group.

It has been suggested that tobacco use is related to unfavourable social and lifestyle behaviours in general [32,33]. By contrast, the snus users investigated here were younger, more physically active, and had higher educational levels than both smokers and those who had never used tobacco, which may reduce their risk of diabetes. We did find that the results persisted after adjustment for a number of factors, including physical activity and education; however, it is possible that the lack of association between snus and Type 2 diabetes is due to residual confounding.

In conclusion, our findings extend to diabetes previous notions that snus is generally less harmful than other tobacco products [25–27,34]. However, even though this is the largest study on snus use and diabetes to date, further studies with an even larger sample size would be necessary in order to rule out modest effects of snus use on the risk of diabetes and effects pertaining to very high consumption.

### **Funding sources**

The ESTRID study was funded by grants from the Swedish Medical Research Council, The Swedish Research Council for Health, Working Life and Welfare, AFA Insurance Company and The Swedish Diabetes Association. ANDIS is funded by grants from the Swedish Medical

Research Council and ALF- Swedish Research Council funding for Clinical research. Funding for ANDIU was provided by the Swedish Medical Research Council, a strategic Research Grant from the Swedish Government (excellence of diabetes research in Sweden-EXODIAB).

The HUNT Study is a collaboration between HUNT Research Centre (Faculty of Medicine, Norwegian University of Science and Technology), Nord-Trøndelag County Council and the Norwegian Institute of Public Health. GlaxoSmithKline Norway supported the Diabetes Study at HUNT2 and HUNT3 financially through the Norwegian University of Science and Technology.

(Opinion 2)  
**Tobacco Additives II**

The SCHEER approved this Opinion for public consultation at the 2nd Plenary on 6 July 2016

**About the Scientific Committees (2016-2021)**

Two independent non-food Scientific Committees provide the Commission with the scientific advice it needs when preparing policy and proposals relating to consumer safety, public health and the environment. The Committees also draw the Commission's attention to the new or emerging problems which may pose an actual or potential threat.

They are: the Scientific Committee on Consumer Safety (SCCS) and the Scientific Committee on Health, Environmental and Emerging Risks (SCHEER). The Scientific Committees review and evaluate relevant scientific data and assess potential risks. Each Committee has top independent scientists from all over the world who are committed to work in the public interest.

In addition, the Commission relies upon the work of other Union bodies, such as the European Food Safety Authority (EFSA), the European Medicines Agency (EMA), the European Centre for Disease prevention and Control (ECDC) and the European Chemicals Agency (ECHA).

**SCHEER**

This Committee, on request of Commission services, provides Opinions on questions concerning health, environmental and emerging risks. The Committees addresses questions on:

- health and environmental risks related to pollutants in the environmental media and other biological and physical factors in relation to air quality, water, waste and soils.

- complex or multidisciplinary issues requiring a comprehensive assessment of risks to consumer safety or public health, for example antimicrobial resistance, nanotechnologies, medical devices and physical hazards such as noise and electromagnetic fields.

**SCHEER members**

Roberto Bertollini, Teresa Borges, Wim de Jong, Pim de Voogt, Raquel Duarte-Davidson, Peter Hoet, Rodica Mariana Ion, Renate Kraetke, Demosthenes Panagiotakos, Ana Proykova, Theo Samaras, Marian Scott, Remy Slama, Emanuela Testai, Theo Vermeire, Marco Vighi, Sergej Zacharov

**ABSTRACT**

The Commission has established a priority list of 15 additives contained in cigarettes and roll-your-own tobacco subject to enhanced reporting obligations. The EU Tobacco Product Directive (TPD) prescribes that Member States shall require manufacturers and importers of tobacco products to carry out comprehensive studies on these additives. The SCHEER was asked to provide guidance on the type and criteria for these comprehensive studies, and the most suitable methodologies to be used. In answer to this request, the current Opinion will guide comprehensive studies for the first list of 15 priority additives, and for additives on future updated lists; it also provides a reporting template. As tobacco additives have no benefits for health or otherwise, but rather promote use and addiction to an extremely toxic product, a risk-benefit analysis is not the appropriate paradigm for assessing the additive. Here, the precautionary principle should come into full force.

In the first part, SCHEER proposes a step-wise strategy, as the most pragmatic and efficient way to proceed in the assessment of the toxic and addictive effects as well as characterising flavour properties, as contributing to attractive effects of tobacco additives. The proposed strategy ensures that testing is minimised. In step 1, an evaluation of the literature available on toxicity, addictiveness and characterising flavour (contributing to attractiveness) for the additive needs to be carried out (step 1). In step 2, this evaluation is extended to the additive's pyrolysis products; if no data are available on the identity of the pyrolysis products, they need to be generated using relevant test conditions. Here, it is important to note that no validated methods exist for the determination of pyrolysis products from tobacco additives, but some indications are given in the Opinion.

In case data received in Step 1 and 2 are not sufficient or robust enough to make the evaluation possible, non-testing methods such as quantitative structure-activity relationship (QSAR) and read across are proposed, followed by *in vitro* approaches addressing the different endpoints to be considered, all of which could be done in Step 3. Regarding types of effects, unless the previous step highlighted some concern for a specific end-point, toxicity should be assessed first, as accepted methods and evaluation frameworks are available, followed by assessing whether a product contains a characterising flavour. Next, addictiveness should be assessed, an effect for which no validated tests are available, although mechanisms underlying addictiveness are known. The issue related to interaction of the additive with other additives/ingredients is also considered.

In addition to proposing specific steps and tests to be considered by industry, some general criteria were also identified. Most importantly, the test outcomes should be relevant for tobacco smoking. This implies that they should be related to actual human exposure to tobacco smoke and to tobacco-induced diseases. Furthermore, comparative toxicity testing strategies, where differences in the effect of the tobacco product with and without the additive are evaluated, are not considered suitable with the currently available methodology. These studies lack discriminative power, and their results cannot be generalised to all products and brands, having a different composition with respect to tobacco type, blend and additives. Comparative studies are also not endorsed to study the effect of additives on addictiveness and inhalation facilitation, for the same reasons. Instead, the effects of the pure additive, and its pyrolysis products, must be considered. For ethical reasons, animal studies are not endorsed to assess the safety of a tobacco additive. Therefore, as a principle, only *in silico* and *in vitro* studies should be

## Tobacco Additives II

---

considered, following the EU policy to ban animal studies for chemicals to be used in voluntary products. Human studies are discouraged. These may be used in case of flavour assessment, but only if the study subjects are not exposed to the harmful smoke emissions of tobacco products.

The major data gaps already identified in Tobacco Opinion 1 for the 15 additives included in the EU Commission priority list have been analysed. Based on this analysis, the activities to be performed upfront have been described. In general, important data gaps for the 15 priority additives are information on addictiveness and attractiveness, as well as on the identity of the pyrolysis products.

Keywords: tobacco, additives, combustion products, cigarettes, roll-your-own, smoking, toxicity, addictiveness, attractiveness, characterising flavour, facilitated inhalation.

Opinion to be cited as:

## 1 MANDATE

### 1.1 Background

The new Tobacco Products Directive 2014/40/EU strengthens the rules regarding the reporting and composition of tobacco products. In addition to tightening the obligations of manufacturers to report on ingredients<sup>1</sup> contained in tobacco products, the Directive regulates permissible additives (or levels thereof) in order to improve the functioning of the internal market whilst guaranteeing a high level of public health.

A) Article 7 of Directive 2014/40/EU foresees in particular the prohibition of the following:

- 1) tobacco products with a characterising flavour (Art 7(1))
- 2) tobacco products containing the following additives<sup>2</sup> (Art 7(6)):
  - a) vitamins or other additives that create the impression that a tobacco product has a health benefit or presents reduced health risks;
  - b) caffeine or taurine or other additives and stimulant compounds that are associated with energy and vitality;
  - c) additives having colouring properties for emissions;
  - d) for tobacco products for smoking, additives that facilitate inhalation or nicotine uptake; and
  - e) additives that have CMR<sup>3</sup> properties in unburnt form.
- 3) tobacco products containing flavourings in any of their components such as filters, papers, packages, capsules or any technical features allowing modification of the smell or taste of the tobacco products concerned or their smoke intensity. Filters, papers and capsules shall not contain tobacco or nicotine. (Art 7(7))
- 4) tobacco products containing additives in quantities that increase the toxic or addictive effect, or the CMR properties of a tobacco product at the stage of consumption to a significant or measureable degree. (Art 7(9))

The provisions outlined above shall apply in the first stage to cigarettes and roll-your-own tobacco. The exemption for other product categories may be removed under certain conditions.

B) Moreover, in line with Article 6 the Commission has to develop and update a **priority list of at least 15 additives** contained in cigarettes and roll your own tobacco by May 2016. This list shall contain additives

- 1) for which initial indications, research, or regulation in other jurisdictions exist suggesting that they have one of the following properties:
  - a) contributes to the toxicity or addictiveness of the products concerned / increases the toxicity or addictiveness of any of the products concerned to a significant or measurable degree;
  - b) results in a characterising flavour<sup>4</sup>;

<sup>1</sup> 'ingredient' means tobacco, an additive, as well as any substance or element present in a finished tobacco product or related products, including paper, filter, ink, capsules and adhesives (TPD 2014/40/EU)

<sup>2</sup> 'additive' means a substance, other than tobacco, that is added to a tobacco product, a unit packet or to any outside packaging (TPD 2014/40/EU)

<sup>3</sup> CMR - carcinogenic, mutagenic or toxic for reproduction

## Tobacco Additives II

---

- 1 c) facilitates inhalation or nicotine uptake; or
- 2 d) leads to the formation of substances that have CMR properties / increases
- 3 the CMR properties in any of the products concerned to a significant or
- 4 measurable degree; and
- 5 2) which are amongst the most commonly used additives by weight or number
- 6 according to the reporting of ingredients.

7 For these priority additives, enhanced reporting obligations will apply in the form  
 8 of comprehensive studies which shall examine for each additive whether it has any of  
 9 the properties 1 a) to d) specified above. Those studies shall take into account the  
 10 intended use of the products concerned and examine in particular the emissions  
 11 resulting from the combustion process involving the additive concerned. The studies  
 12 shall also examine the interaction of that additive with other ingredients contained in the  
 13 products concerned. The results of these studies shall assist Member States and the  
 14 Commission in their enforcement efforts regarding Art. 7.

15 The SCENIHR published a scientific Opinion on the attractiveness and addictiveness  
 16 of additives in 2010<sup>5</sup>. In light of the time that has passed since then and the need to  
 17 address the current regulatory requirements, the SCENIHR has been asked to address  
 18 the questions outlined in the Terms of Reference below.

19

---

<sup>4</sup> 'characterising flavour' means a clearly noticeable smell or taste other than one of tobacco, resulting from an additive or a combination of additives, including, but not limited to, fruit, spice, herbs, alcohol, candy, menthol or vanilla, which is noticeable before or during the consumption of the tobacco product (TPD 2014/40/EU)

<sup>5</sup> [http://ec.europa.eu/health/scientific\\_committees/emerging/docs/scenihr\\_o\\_031.pdf](http://ec.europa.eu/health/scientific_committees/emerging/docs/scenihr_o_031.pdf)

## 1.2 Terms of reference

The main purpose of the requested scientific Opinion is to assist the Commission in identifying the additives that should be put on the priority list. The scientific Opinion can, however, also provide useful input for Member States and the Commission in their broader regulatory/enforcement activities (e.g. setting thresholds/banning of additives), in particular in areas where the knowledge base may currently still be limited. In particular, the Committee is asked the following:

### **Opinion 1:**

1. Based on scientific evidence (including a review of relevant scientific data) and other relevant information currently available (initial indications, regulation in other jurisdictions), the Committee is asked to identify - for each category separately - those additives that fall/are suspected to fall within the scope of the following categories:

- a. Contributing to the toxicity or addictiveness of the products concerned / increasing the toxicity or addictiveness of any of the products concerned to a significant or measurable degree;
- b. Resulting in a characterising flavour;
- c. Facilitating inhalation or nicotine uptake;
- d. Leading to the formation of substances that have CMR properties / increasing the CMR properties in any of the products concerned (cigarettes/roll-your-own) to a significant or measurable degree;<sup>6</sup>

The assessment should include for each of the additives identified a comprehensive description of the type of information supporting its identification as well as a description and quantification of the strength of the observed characteristic and the strength of the available evidence supporting this finding<sup>7</sup>. If the Committee identifies more than 20 additives for a category, the Committee is entitled to prioritise in the light of the criteria set out in this section. In this case, the description is limited to the top 20 additives per category, whilst the other additives can be listed without description.

The Committee is asked to also consider in its assessment the interaction with other ingredients contained in the products concerned and the emissions resulting from the combustion process involving the additive concerned as well as the intended use of the products. Relevant knowledge gaps should be identified.

As far as relevant information is available, the Scientific Committee is asked to identify within its assessment the most commonly used additives by weight or number. If additives belong to a single group of substances with identical or very similar properties, both the group of substances and the list of substances falling into that group shall be presented and the most relevant substance(s) within that group identified.

<sup>6</sup> If an additive is included in Annex VI of Regulation (EC) No 1272/2008, its CMR-classification should be provided and considered as appropriate. Additives that have CMR properties in unburnt form should be identified/listed, but do not require a comprehensive description.

<sup>7</sup> Registrations/assessments of relevant substances under Regulation (EC) No 1907/2006 should be provided and considered as appropriate.

---

## Tobacco Additives II

---

1 When examining the composition of tobacco products and the use of individual  
2 substances, the Scientific Committee is invited to consult the data on additives reported  
3 by the tobacco industry under the Tobacco Products Directive 2001/37/EC, but may also  
4 consider additional data sources. Furthermore, the Committee is invited to consider  
5 during their assessment the lists of additives permitted/prohibited for use in tobacco  
6 products as implemented by certain Member States.

7 2. Based on its assessment in point 1, the Committee is asked to establish a list of  
8 a minimum of 20 and maximum of 30 additives that are suitable/recommended to be  
9 added to the priority list of additives in line with Article 6 of TPD 2014/40/EU. When  
10 establishing the list, the Committee shall consider the public health risks associated with  
11 the additives (actual or suspected), strength of the available evidence and to the extent  
12 possible, the frequency of use of the additives in tobacco products. The Committee  
13 should indicate as far as possible rankings of additives in light of the above and provide  
14 an explanation for its ranking<sup>8</sup>.

15 ***Opinion 2:***

16 3. Furthermore, the Committee is asked to advise the Commission on the type and  
17 criteria for comprehensive studies that should be requested from manufacturers to  
18 assess the relevance of the individual additives, considering inter alia the knowledge  
19 gaps identified in point 1 above and the interaction of the additive with other  
20 additives/ingredients. Advice is also sought on the most suitable methodologies to be  
21 used (including a structure of the reports that can be peer reviewed).

---

<sup>8</sup>Substances belonging to the same group of identical/very similar substances should be considered jointly.

## 2 SCIENTIFIC RATIONAL

### 2.1 Introduction

In response to the Commission's requests, the SCENIHR adopted Opinion 1 (Tobacco Additives I), in which 48 single chemicals were listed as priority additives, which met the 30 entries maximum limit because some chemicals with very similar structures (i.e. aliphatic gamma-lactones, including 8 chemicals) and/or properties (e.g. weak acids, including 8 group members) were grouped together. They were selected on the basis of two initial criteria: the frequency of use in different brands and the amounts used in cigarettes, then further screened based on their hazardous properties, because they have or are suspected to have one or more of the following properties:

- a. Contributing to the toxicity or addictiveness of the products concerned / increasing the toxicity or addictiveness of any of the products concerned to a significant or measurable degree;
- b. Resulting in a characterising flavour;
- c. Facilitating inhalation or nicotine uptake;
- d. Leading to the formation of substances that have CMR properties / increasing the CMR properties in any of the products concerned (cigarettes/roll-your-own) to a significant or measurable degree.

On the basis of these criteria:

- 17 substances were identified because they fall or are suspected to fall in the category: toxic in unburnt form, among which 6 are suspected of CMR potential, which were ranked highest on the suggested list because the Tobacco Products Directive foresees the prohibition of additives that have CMR properties in unburnt form.
- 20 substances were identified because they are known or suspected of forming irritant, toxic and/or CMR chemicals after combustion including sugars, sugar-containing additives and cellulose.
- 14 substances were identified because they are suspected of facilitating inhalation or of increasing nicotine uptake.
- 19 substances were identified because they show a characterising flavour, a factor potentially contributing to attractiveness.

Since SCENIHR was asked to prioritize the selected chemicals to the best of its ability, three groups were identified. In addition to the 6 chemicals suspected of CMR potential, menthol was included in the 'highest priority group'.

A second group was identified based on the possibility of forming CMR compounds after combustion.

All the remaining identified additives are categorised in the third group, although it was not possible to rank them on the basis of their specific hazard profile and the only possibility was to use content/frequency ranking as a possible criteria for prioritisation or a combination of more than one of four characteristics provided for in Article 6.

On May 18, 2016, the Commission adopted the Commission Implementing Decision (EU) 2016/787 laying down a priority list of additives contained in cigarettes and roll-your-

## Tobacco Additives II

---

own tobacco subject to enhanced reporting obligations<sup>9</sup>, identifying 15 chemicals among those listed in the SCENIHR Opinion (Additives used in tobacco products; Tobacco Opinion 1) adopted in January 2016.

In this Opinion 2, on the basis of the knowledge gaps mentioned in the next section, and after revising the available open literature and approaches taken by International Agencies, SCHEER provides advice to the Commission on the type and criteria for comprehensive studies that should be requested from manufacturers to assess the relevance of the individual additives, proposing a step-wise strategy (Section 3.4). The issue related to interaction of the additive with other additives/ingredients is also considered.

It should be noted that, by contrast to adding them to medicines or food, for example, additives in tobacco products have no health or other benefits for the consumer. On the contrary, by making smoking more attractive, they promote an extremely unhealthy behaviour. Therefore, a risk-benefit analysis is not the appropriate paradigm for assessing the additive and as such the level of proof of safety must be set much higher than for other products. Considering that for many additives the toxicological information relevant to inhalation is often scant, it is a SCHEER recommendation that the precautionary principle as a quintessential element of preventive toxicology should come into full force (Reichl and Schwenk, 2004). It stipulates that a reasonable suspicion of toxicity is sufficient to deny approval of such a substance (DKFZ, 2010). The same reasoning applies to the addictive and attractive effects of tobacco additives, as they will indirectly lead to adverse health consequences by increasing consumption of the product.

In addition to the general strategy, the major data gaps already identified in Tobacco Opinion 1 have been analysed to determine the most appropriate steps (and end-points) to be carried out and then used for the evaluation (Section 3.5), in order to speed up the process, making possible testing feasible within the 18-month time-frame. To give an example, for the 6 chemicals for which a genotoxic potential could not be ruled out for the unburnt form, the first step will be to evaluate their genotoxicity: in case of positive results, no other testing will be necessary, since according to the TPD they will automatically be banned for use as tobacco additives. In case of negative results, they will enter the general strategy of testing and be considered as would any other compound.

---

<sup>9</sup> <http://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:32016D0787&from=EN>

## 2.2 Knowledge gaps identified in Opinion 1

There was generally scant toxicological information regarding tobacco additives analysed for Opinion 1, and the available information was often limited to the oral route of exposure, especially for flavouring substances that are used by the food industry, or, to a lesser degree, to the dermal route, for substances that are also commonly used in cosmetic products. Data on the effects of additives in tobacco following inhalation is generally not available, although this is the most relevant exposure route. Indeed, the additives are either transferred to inhaled smoke in pure form, or are combusted and converted via pyrolysis into potentially toxic products. Because there was also little data on their kinetic behaviour, it was difficult, if not impossible, to make route-to-route extrapolation for additives.

A general scarcity of information was observed regarding the actual level of exposure to additives both in the unburnt form in tobacco products and resulting from combustion – including data on pyrolysis. This is particularly relevant since toxic combustion products generated upon pyrolysis of additives have the potential to increase the exposure to toxic substances and thus increase the health hazard associated with cigarette smoking (National Institute for Public Health and the Environment, 2012). The fate of the additive depends on its physico-chemical properties such as its volatility and reactivity, the design of the cigarette and the smoking topography of the user. The additive may be distilled from the tobacco rod, and end up in smoke intact, or it may be (partly) combusted. In case of (partial) pyrolysis, not only the unburnt additive is relevant, as the smoker will be exposed to the pyrolysis products as well. In the tobacco matrix, either the intact additive or its pyrolysis products may react with other additives, tobacco- or smoke components (pyrosynthesis). For instance, only minor amounts of the non-volatile sugars in tobacco (approximately 0.5% of glucose and sucrose) are transferred unchanged into the mainstream smoke, whereas the major part will combust, pyrolyse or participate in pyrosynthesis processes (Talhout *et al.*, 2006).

Although for most tobacco additives, direct information about their possible contribution to addictiveness and characterising flavours does not exist, information can be derived from the mode of action of the additive (e.g. addictiveness can be related to increased nicotine bioavailability or to local anaesthetic effects facilitating the inhalation of tobacco smoke).

Generally speaking, the scarcity of information on exposure and on toxic effects make risk assessment difficult, if not impossible.

## 2.3 Methodology

### 2.3.1 Development of the general approach to assess the effects of tobacco additives

Given the fact that additives in tobacco products have no health or other benefits for the consumer, but rather promote an extremely risky behaviour, risk-benefit evaluations are not appropriate. Based on evaluation of approaches for regulation of other types of components, the SCHEER concluded that a step-wise approach is the most pragmatic and efficient way to proceed in the assessment of the toxic, addictive and attractive effects of tobacco additives. The tiered approach proposed by DKFZ (DKFZ, 2010) was used as a starting point, and adapted to include the evaluation of attractive

1 and addictive effects of additives. The order of the steps has been proposed in such  
2 a way to minimise testing. First, an evaluation of the available literature is proposed,  
3 next, non-testing methods such as quantitative structure–activity relationship (QSAR)  
4 and read across are employed, followed by *in vitro* approaches. Regarding types of  
5 effects, toxicity is assessed first, as CMR chemicals are not allowed, and accepted  
6 methods and evaluation frameworks are available for toxicity testing, followed by  
7 characterising flavours, because accepted methods and evaluation frameworks are  
8 available. Finally, addictiveness is assessed, and since no validated tests are available  
9 here, the assessment can be guided by the knowledge of the mechanism of action.

### 10 **2.3.2 Addressing the major data gaps identified in Opinion I for the** 11 **priority list additives**

12 The major data gaps already identified in Tobacco Opinion 1 for the 15 additives included  
13 in Commission Implementing Decision (EU) 2016/787 have been analysed. Based on  
14 the data gaps described in the 'Rationale for inclusion' in Opinion 1, the activities to be  
15 performed upfront have been described. Then on the basis of the obtained results, if  
16 the additive does not meet the criteria for exclusion as an additive listed in art. 7 of  
17 the TPD, it can be subject to the general evaluation step-wise procedure described in  
18 the Opinion.

### 19 **2.3.3 Information collection**

20 Information on guidance for the data collection and tests to be performed in the different  
21 steps of the step-wise approach was collected on available open literature/websites and  
22 from documents by other Committees/International Organisations (e.g. WHO, EPA,  
23 EFSA, JECFA).

### 24 **2.3.4 Information evaluation**

25 For this Opinion on tobacco additives, the available information was analysed to identify  
26 tests and testing structures that are appropriate for the assessment of the toxic,  
27 addictive and attractive effects of tobacco additives.

## 2.4 Step-wise approach to assess the toxic, addictive and attractive effects of tobacco additives

A pragmatic and efficient step-wise approach is suggested, in order to assess the toxic, addictive and attractive effects of tobacco additives. Tobacco industry has the burden of proof that an additive does not fall within the scope of the four categories mentioned in the terms of reference and it is tobacco industry's responsibility to deliver data. The data need to be evaluated by independent scientific bodies with expertise in risk assessment of the toxic, addictive, and attractive properties of chemicals.

In order to limit the financial and administrative burden for industry and authorities, as well as the amount of literature evaluation and testing by industry, and subsequent evaluation of the submitted reports by independent institutes, the formation of consortia and joint reports by industry is endorsed.

For the toxicological evaluation of additives in tobacco products, the tiered approach proposed by DKFZ (DKFZ, 2010) is a good starting point. This approach has been slightly adapted and widened to allow for the evaluation of attractive and addictive effects of additives (see Figure 1). This is because apart from toxicity, tobacco additives may indirectly increase tobacco-related harm by increasing the consumption rate of tobacco products, either by making the product more attractive to the consumer (e.g. by resulting in a characterising flavour, and by facilitating inhalation), or by enhancing its addictiveness (National Institute for Public Health and the Environment, 2012). As far as possible, this possibility has to be considered. Although a standardised methodology is not available, it is possible to derive information from the mechanism of action of the additive (e.g. addictiveness can be related to increased nicotine bioavailability or to local anaesthetic effects facilitating the inhalation of tobacco smoke; see the possible mechanism in the SCENIHR Opinion, 2010).

Whenever the evaluation of the additive in the unburnt form gives rise to any concern in relation to art 7 of the TPD (e.g. foreseeing the prohibition of additives having CMR properties) based on data collected in Step 1, the evaluation is stopped, meaning that the additive does not meet the requirement of the TPD. The same rule is applied to Step 2 for the pyrolysis products. In these cases, industry can proceed to step 4, reporting.

In case data are not available, or are not sufficient or robust enough to make the evaluation possible, the procedure should go to the next step.

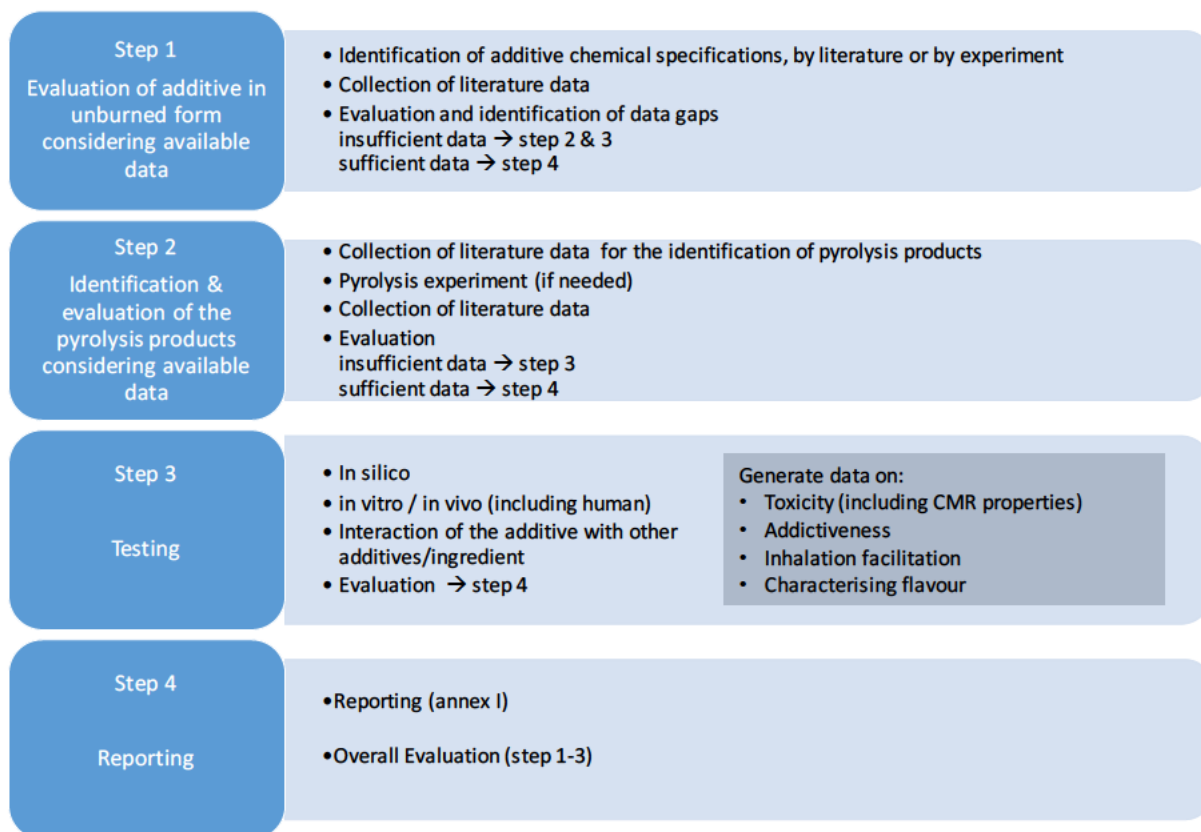

In case of high uncertainty about the evaluation based on available data, there are two possible options:

- Application of the precautionary principle
- Delivering of additional data (i.e. via Step 3) by tobacco industry.

Step 2 is analogous to Step 1 but related to the pyrolysis products; the two steps can take place concurrently if this is more efficient and saves time. The collection of available data is mandatory in order to priorities the most appropriate end-point(s) to be assessed in step 3, to limit useless testing.

## Tobacco Additives II

**Figure 1.** Step-wise approach to be applied to the assessment of the toxic, addictive and attractive effects of tobacco additives. For terminology, please refer to the text.

This procedure could be applied to single individual additives; if necessary additives could be grouped, following rules previously established in other fora to evaluate e.g. groups of food flavouring at EFSA<sup>10</sup> or groups of chemicals in Regulation (EC) No 1907/2006 i.e. REACH (to apply the read-across principles)<sup>11</sup> in order to limit the use of animal testing (as requested in art. 13). The ECHA provides practical guidance on the issue (available at the above-mentioned website link); however, to this aim, the approach described in the OECD GUIDANCE ON GROUPING OF CHEMICALS No. 194<sup>12</sup> is recommended.

The approach described in the OECD guidance document (GD) is to consider closely related chemicals as a group, or category, rather than as individual chemicals, for assessing the hazards of chemical substances, increasing efficiency and improving animal welfare. Since the technique of assessing groups of substances is an evolving science, the GD is revised periodically and it is therefore compulsory that the tobacco industry follows the most updated version when applying it. As it is recommended by the GD itself, early consultations between industry and authorities are recommended to ensure that any regulatory requirements are fulfilled.

<sup>10</sup> <https://www.efsa.europa.eu/en/topics/topic/flavourings>

<sup>11</sup> <http://echa.europa.eu/support/grouping-of-substances-and-read-across>

<sup>12</sup> GUIDANCE ON GROUPING OF CHEMICALS, SECOND EDITION Series on Testing & Assessment No. 194 (2014) available at [http://www.oecd.org/officialdocuments/publicdisplaydocumentpdf/?cote=env/jm/mono\(2014\)4&doclanguage=en](http://www.oecd.org/officialdocuments/publicdisplaydocumentpdf/?cote=env/jm/mono(2014)4&doclanguage=en)

The GD outlines a process for grouping chemicals to include the identification of analogues/members of categories, the mechanistic basis for using analogues or chemical categories and the robustness of both approaches. The GD also describes the use of (Q)SARs for data evaluation and data-gap filling (read-across, trend analysis and (Q)SARs).

#### **2.4.1 Step 1: Evaluation of the additive in unburnt form**

The first step starts with the identification of the additive chemical specifications, by literature or by experiment (for the physico-chemical characterization, if not available, data can be obtained following the OECD or ISO test guidelines to this purpose). This initial step is absolutely necessary in order to identify the nature of the additives and comprises also qualifying and quantifying of any impurity present. CAS numbers need to be provided for all relevant chemicals (additives and impurities). The chemistry and specification of a substance (or mixture of substances), in terms of chemical structure(s) and physico-chemical properties is also asked for in other legislations, e.g. for food additives.

It may not always be possible to fully characterise natural extracts, but as much information as possible is required to understand the extent to which variability in composition is controlled during manufacture. Data on the chemical composition of a natural extract additive should be provided by industry with emphasis on the concentrations of constituents of relevance; this includes the concentrations of compounds classified according to their chemical structure (e.g. flavonoids, terpenoids, alkaloids, etc.), constituents being characteristic for tobacco additives (chemical fingerprint, markers). Information on maximum levels for microorganisms and possible contaminants, including e.g. heavy metals, mycotoxins, pesticide residues and polycyclic aromatic hydrocarbon (PAH) residues, should be provided (EFSA, 2012).

Then, all available information on the additive in unburnt form is collected and evaluated. This includes open literature on peer-review journals as well as grey literature, including JECFA, EFSA and FEMA data or data coming from any other regulatory request, in case the additive is used in other contexts.

This step allows the collection of available information on the additive in its unburnt form, useful for its risk assessment. In addition, it allows the identification of the major data gaps to be addressed in Step 3, especially with regard to toxicity, characterising flavour (and other possible factors contributing to attractiveness) and addictiveness data.

For future reference by the regulator, industry is also asked to indicate which additives are closely related regarding chemical structure, functions, purpose and effects. An example here is menthol, which is functionally closely related to e.g. menthol derivatives, wintergreen and spearmint.

##### **2.4.1.1 Collection of literature data**

Whenever possible, all information already available on the toxicity of the additive should be collected, used and evaluated before any testing is initiated. Some knowledge on the toxicity of tobacco additives exists; however, much less is known on their attractiveness and addictiveness. Open literature as well as grey literature should be included and if studies have been already performed in view of seeking approval of the same chemical

---

Tobacco Additives II

---

for uses other than tobacco additive, a letter of access should be acquired, in order to avoid repeating of the same tests.

Initial electronic literature searches with appropriate key words/dates should be a starting point for data gathering. The databases and search engines used may include for example PubMed, Web of Science, Scopus, Toxline, Chemical and Biological Abstracts, and Google Scholar. The data search methods will identify many papers that potentially could be used. A first screening is then needed in order to focus on those relevant for the specific purposes, using appropriate inclusion/exclusion criteria. Articles that do not appear to meet the inclusion criteria should be excluded from further analysis. To apply a standardised methodology it is recommended that the literature search strategy and selection criteria (inclusion/exclusion) for the review are based on the EFSA Systematic Review Guidance (EFSA Journal 2010; 8(6):1637).

The methodological quality of the selected paper should also be addressed, including the design, execution, analysis and reporting of the study. Expert judgement is vital in the assessment of the quality and the interpretation of data therefore the appropriate identification and selection of relevant publications is extremely important. When possible (e.g. for toxicity studies) this screening should be based on Klimisch scoring.

The acceptance of each publication that is considered to be relevant should be based on the quality and relevance criteria summarised in by SCENIHR (2012).

All selected publications of potential importance should be subject to similar treatment in the evaluation process. Positive and negative studies should be evaluated using similar procedures and criteria and considered of similar importance if the quality is judged to be comparable. In positive studies the evaluation needs to consider both causal and non-causal explanations of the results. For example, one key question would be "with what degree of certainty can one rule out the possibility that the observed positive result is produced by bias, e.g. confounding or selection bias, or chance?". In the case of negative studies, it is necessary to assess the certainty with which it can be ruled out that the lack of an observed effect constitutes evidence against a hazard or whether it could result from (masking) bias, e.g., too small exposure contrasts, too crude exposure measurements, too small exposure groups/populations, or chance. Consideration should also be given to the possibility of a publication bias i.e. that positive findings are more likely to be published than negative findings.

It is recommended that the whole data set, judged as relevant, reliable, and of good quality, should be used for the (risk) assessment of the tobacco additive and its pyrolysis products, if any. Different approaches for assessment of whole data sets, referred to as weight of evidence evaluation or systematic review (often used interchangeably), have been promoted (Koustas *et al.*, 2014; Rooney *et al.*, 2014; European Food Safety Authority, 2010; IARC, 2006). In general terms, these approaches are processes of summarising, synthesising and interpreting a body of evidence to draw conclusions, e.g. regarding the relationship between a chemical exposure and an adverse health effect. The WoE approach promotes the use and integration of information from all available evidence.

Unfortunately, formal procedures and consistent terminology for weight of evidence processes are lacking, although a weight of evidence evaluation is mentioned in the REACH regulation, the Biocides directive, the Cosmetics regulation, and the regulation for Classification, Labelling and Packaging (CLP). Some guidance documents are only available for industrial chemicals or contaminants in food (Ågerstrand and

## Tobacco Additives II

---

Beronius, 2015). However, a number of organisations have established their own frameworks for assessing/evaluating evidence, including SCENIHR (2012), and the work is still in progress in both SCHEER and EFSA. Since the approach is rapidly evolving, it is compulsory that in applying it, the Tobacco Industry follows the most updated version.

As indicated above, it is possible to apply substance grouping of read-across principles: this approach uses relevant information from analogous ('source') substances to predict the properties of 'target' substances. The application and reporting of this approach as described in section 3.4.1.1 is recommended; if applied correctly, there is no need to have specific information on every additive.

In order to collect data on addictiveness and attractiveness, all investigations on possible related mechanisms should be considered. In this respect, an emerging approach is the adverse outcome pathway (AOP) – a framework designed to conceptually link a molecular initiating event to an adverse outcome of relevance to risk assessment (Ankley *et al.*, 2010). The AOP framework allows for a better understanding of the mechanistic linkages between cellular responses and downstream impacts on apical outcomes that are of concern within a regulatory context (Villeneuve and Garcia-Reyero, 2011). Potential practical uses of AOPs also include the above-mentioned grouping of common chemicals for read across (not only based on chemical structures but on biological activity), identification of research and data gaps, serving as a framework for regulatory priority setting, and informing hazard characterization and risk assessment (Becker *et al.*, 2015). AOP methodology may be useful in elucidation of molecular basis for addictiveness of tobacco products e.g. role of pH changes on nicotine absorption, MAO-A inhibition, Dopamine (DA) release and turn over, CYP metabolism and inhibition (for details see paragraph 3.4.3.5). Accordingly, the same apply to attractiveness investigation (for details see paragraph 3.4.3.6). OECD developed a guidance document outlining methods and best practices for creating and assessing AOPs, in which it calls for the assessment of an AOP's weight of evidence (OECD, 2013; AOP-Wiki, 2014). AOP wiki represents a joint effort between the European Commission – DG Joint Research Centre (JRC) and the U.S. Environmental Protection Agency (EPA). This serves as one component of a larger OECD-sponsored AOP Knowledge Base effort and represents the central repository for all AOPs developed as part of the OECD AOP Development Effort by the Extended Advisory Group on Molecular Screening and Toxicogenomics.

### 2.4.1.2 Evaluation

Whenever the evaluation of the chemical in its unburnt form give rise to any concern regarding CMR properties, the evaluation is stopped, meaning that the additive does not meet the requirement of TPD art. 7, and can directly proceed to Step 4.

Collected data gives information regarding the possibility for the additive to fall into one or more of the four categories:

- a) Contributing to the toxicity or addictiveness of the products concerned/increasing the toxicity or addictiveness of any of the products concerned to a significant or measurable degree;
- b) Resulting in a characterising flavour;
- c) Facilitating inhalation or nicotine uptake;
- d) Leading to the formation of substances that have CMR properties / increasing the CMR properties in any of the products concerned (cigarettes/RYO) to a significant or measurable degree.

In case data are unavailable, insufficient or not robust enough to make any evaluation possible, the procedure should go to Step 3. In case of uncertainties about the evaluation in the presence of a health concern, the precautionary principle can be applied or alternatively tobacco industry could proceed to Step 3.

## **2.4.2 Step 2: Evaluation of the pyrolysis products**

In the second step, information available on the identification of pyrolysis products of additives must be collected and evaluated. This can be done on the basis of literature data (see section 3.4.2.2 for criteria), but in case no sufficient data (in quantitative or qualitative terms) are available, the second step foresees that pyrolysis studies need to be performed in realistic, standardised experimental conditions (see section 3.4.2.2). Then available literature data on the toxicological profile, attractiveness or addictiveness on the identified pyrolysis products should be collected, as described in Step 1 for the chemical in the unburnt form.

### **2.4.2.1 Collection of literature data**

Literature data on the pyrolysis products of additives is collected in the same way as described in Step 1.

### **2.4.2.2 Pyrolysis studies (if needed)**

To identify the compounds formed during the combustion process of a tobacco additive, tobacco industry in general performs pyrolysis studies on a comparative basis where a research cigarette is machine smoked with and without the additive present (Talhout *et al.*, 2006). Burning (smoking) the tobacco that contains a specific amount of the additive and subsequent analysis of selected smoke components is described for many different additives (Baker *et al.*, 2004a; Baker *et al.*, 2004b, c; Carmines, 2002; Rustemeier *et al.*, 2002). However, subtle differences between the selected smoke components will not be noticeable, and it is not feasible to screen the effect on all 6000 known smoke components, hence usually only the so-called Hoffmann analytes are screened. Given the complexity of cigarette smoke, it is difficult to identify individual materials that may result from the pyrolysis of ingredient mixtures unless radioactively labelled additives are used, but that method is sophisticated and expensive. Furthermore, this method cannot determine whether the additive is a precursor or a catalyst for the formation of a certain smoke component (Torikai *et al.*, 2005).

Pyrolysis, on the other hand, is a useful technique for evaluating materials used at low levels, where it is unlikely that smoke chemistry assays could detect a change. Therefore, combustion processes in a burning cigarette have also been simulated with pyrolysis methods (Baker *et al.*, 2004b; Busch *et al.*, 2012; Lee *et al.*, 2007).

This technique is useful as a first screening of potential pyrolysis products, their thermal stability and the temperature at which they are formed (Baker and Bishop, 2004). However, the pyrolysis conditions only approximate the burning cigarette with regard to temperature and atmosphere and make no allowance for the presence of other tobacco and/or smoke components that may interact with the additives. Pyrosynthesis processes related to the tobacco matrix will not occur when the additive is pyrolysed as a single component outside of the tobacco matrix. When it is suspected that such reactions will occur, one may consider pyrolysing a simple mixture containing the additive together with the component with which reaction is foreseen (either with the component itself or with its pyrolysis products. For instance, micro-vial pyrolysis of a glucose/proline mixture

## Tobacco Additives II

resulted in formation of Amadori intermediates, important in the formation of (Maillard) products that influence the aroma (Mitsui *et al.*, 2015). Pyrolysis was performed at 700 °C, approximating the temperature of the pyrolysis zone of a burning cigarette, for 10 s under atmospheric conditions (headspace gas in vial not replaced by an inert gas).

Pyrolysis studies can be performed under a given set of experimental conditions that need to resemble processes in a burning cigarette in terms of e.g. temperature, rate of temperature change, and atmosphere (amount of oxygen). During the cigarette-burning process, the temperature of the tobacco and the burning cone can range from room temperature up to 900 °C, and the amount of oxygen can range from 0 to 18%. It is important that the design of the pyrolysis study reflects the conditions of burning cigarettes with oxygen levels ranging from 0% to 14% and the temperature in the burning zone ranging from ambient temperature to 900 °C (Baker and Bishop, 2004; Stotesbury *et al.*, 1999; Torikai *et al.*, 2004).

Many studies tried to simulate the processes during smouldering and combustion. Stotesbury performed pyrolysis at 14 sets of pyrolysis conditions: temperatures between 200 °C and 700 °C in 2 % and 10 % oxygen, and at 800 °C and 900 °C in 2 % oxygen. Baker used an atmosphere of 9% oxygen in nitrogen, arguing that this is the average amount throughout the pyrolysis/distillation zone inside the burning cigarette during a puff. From an initial temperature of 300 °C, to simulate the smouldering before taking a puff, the sample is heated at 30 °C s<sup>-1</sup> to 900 °C, and kept for 5 seconds, to simulate the maximum duration of the high-burning zone temperature during puff under extreme human smoking conditions. According to Baker, 30 °C s<sup>-1</sup> is the approximate mean heating rate throughout the pyrolysis/distillation zone during a puff. This seems rather slow, as that would imply it would take 20 seconds before the maximum temperature is reached, whereas a human puff only takes one or two second. However, most studies are performed with a similar heating rate (Torikai *et al.*, 2004). Purkis *et al.* programmed the temperature from 300 to 900 at 25 °C per second to reflect cigarette smoking and give an appropriate set of conditions to limit artifact formation (Purkis *et al.*, 2011). It is important that the reaction vial is not closed, so that the additive can distil away at lower temperatures.

Flash pyrolysis is performed when the sample is rapidly inserted in a pre-heated furnace that is already at the highest temperature, for instance at the temperature range of 200–300 °C to simulate cigarette smouldering (Zhou *et al.*, 2011). Time of flight spectroscopy allows for almost real time sampling, enabling identification of reactive compounds before being degraded (Hertz-Schunemann *et al.*, 2015)(Busch *et al.*, 2012).

Taking into account the studies described above, the SCHEER recommends the following experimental design in most cases performed by tobacco industry:

Thermal degradation (pyrolysis, pyrosynthesis and combustion products) of each additive is to be studied under different reaction regimes (inert and 2-14% oxygen) over the temperature range 200–900 °C. The thermal degradation products of two different pyrolysis conditions should be identified:

(1) upon gradually heating the sample from 200–900 °C and

(2) conventional pyrolysis, in which a new sample is pyrolysed at minimally 3 different temperatures (~ 300°C, 600°C and 900°C).

Pyrolysis experiments should be carried out at least in triplicate. Chemical analysis of the components in the pyrolysate needs to be performed with state of the art techniques

## Tobacco Additives II

---

in the field of GC-MS and LC-MS, as appropriate for the specific additive. The World Health Organization in its report to the Sixth Conference of the Parties<sup>13</sup>, identified eight non-exhaustive lists of toxicants: Health Canada, RIVM, USA FDA, Counts, Dybing and Fowles, Hoffman analytes, Philip Morris-Australian brands, and Philip Morris-Canadian brands. These toxicants need to be indentified and quantified, if present, using analytical reference standards. Tobacco-specific components, such as nitrosamines and alkaloids, are not expected to be present.

For additional components, not on these lists, the following procedure is advised. For identification purposes, library software can be used, such as the Automated Mass Spectral Deconvolution and Identification System (AMDIS) software. Components with a peak-to-peak signal-to-noise ratio below three can be discarded. Also, components with a probability of correct identification below 70% can be excluded.

If components with a toxicological hazard are identified, their identification needs to be confirmed and their amount needs to be quantified using analytical reference standards.

Apart from components that may increase the toxicity, specific attention needs to be given to components that have addictiveness-enhancing properties, flavouring properties, or inhalation facilitation properties (e.g. anaesthetic and/or bronchodialating properties).

### 2.4.2.3 Evaluation

Again, when the available information is considered reliable and robust enough concening both the identification of pyrolysis products and on their toxicological, addiction, and attractiveness profile, a possible decision (positive or negative) may be reached. For instance, if it is demonstrated that compounds proven to have CMR properties are generated from pyrolysis of an additive, this additive will not meet the TPD requirement. Again, when caase data are unavailable, insufficient or not robust enough to make any evaluation possible, the procedure should go to Step 3. In case of uncertainties about the evaluation in the presence of a health concern, the precautionary principle can be applied, or alternatively tobacco industry could proceed to Step 3.

### 2.4.3 Step 3: Testing and evaluation of results

The third step is related to the testing of additives or their pyrolysis products, according to methods accepted by other regulations. The outcomes of tests must be related to actual human exposure and tobacco-induced diseases, and be relevant not only for subchronic, but also for chronic exposure in intermittent use sessions (Johnson *et al.*, 2009).

A relevant test design will not only consider methods to investigate toxicity, but also characterising flavour and addictiveness. Therefore information related to the known mechanisms that contribute to attractiveness or addictiveness should be collected.

Based on expert judgement of the major data gaps with regard to toxicity, characterising flavour (as contributing to attractiveness) and addictiveness data identified in Step 1, it must be decided which endpoint to start with. This will generally be the endpoint for which most evidence is available of a potential concern. If no priority concerns have

---

<sup>13</sup> [http://apps.who.int/gb/fctc/PDF/cop6/FCTC\\_COP6\\_14-en.pdf](http://apps.who.int/gb/fctc/PDF/cop6/FCTC_COP6_14-en.pdf)

## Tobacco Additives II

been identified, it is advised to start with toxicity, as in that case, accepted *in vitro* tests are available and there are frameworks for interpreting the results.

This step will also address the possible interactions, at chemical level (e.g. pyrolysis) and for the toxicological part based on the MeA/MoA.

#### 2.4.3.1 Comparative paradigms are not endorsed

In order to provide a relevant outcome to the question of whether an additive contributes to the toxicity, attractiveness, or addictiveness of the tobacco product, the study design must adhere to some methodological criteria. It must be noted that comparative testing strategies, where differences in effect of the tobacco product with and without the additive are evaluated, are not considered suitable at the moment given the current toxicity tests and available methodology. The emissions of tobacco products are highly toxic, in particular regarding cigarette smoke (Kienhuis *et al.*, 2016). Due to the high intrinsic toxicity of tobacco products, it is challenging to demonstrate any differences, whether they be increases or decreases, induced by an additive. Due to the high toxicological activity of both the test product (tobacco product with additive) and the control (tobacco product without additive) in comparative testing strategies, the discriminatory power that can be obtained in toxicity assays may not be sufficient (COT/COM/COT, 2009; DKFZ, 2010; Oldham *et al.*, 2012). Very sensitive tests would be required, with a clear dose-response relationship, in order to show any differences from these high background effects. As such tests are not currently available, no comparative studies (tobacco product with and without additives) will be considered, since these studies lack discriminative power. In line with this, the Committee on Carcinogenicity of Chemicals in Food, Consumer Products and the Environment (COC, 2009) concluded: *"The Committee considered that the available studies used to assess the contribution of individual or mixed ingredients or additives to the overall toxicity of tobacco products are inadequate to assess the risks posed by conventional cigarettes, so it is not possible to assess the modulation of that risk resulting from inclusion of additives. The relationship between effect (an increase in biomarker) and exposure is also poorly understood. Furthermore, it is possible that additives might alter smoker behaviour, such as to increase product use; this increased exposure would be likely to result in an increased risk."*

Furthermore, an international Working Group on Tobacco Additives (WG), assigned by the Brazilian regulatory agency ANVISA, assessed many industry-sponsored studies addressing the effects of mixtures of commonly used additives on cigarette smoke chemistry and toxicity. Although industry claimed that additives have no effect on the levels of chemical components of cigarette smoke and toxicity, the WG concluded that the available data were insufficient to accept the tobacco industry's claims that additives do not increase the inherent toxicity of tobacco smoke (Ferreira *et al.*, 2015; Working Group on Tobacco Additives, 2014): *"Given the current toxicity tests and test designs, it is not yet possible to determine whether or not addition of specific ingredients (tobacco additives) to tobacco products adds to tobacco mainstream smoke's inherent toxicity. This is because tobacco itself is already quite toxic, and any added toxicity is difficult to detect within the current test designs used by tobacco industry, i.e. combinations of in vitro testing and animal testing."*

For the future, tests are needed that are sensitive enough to assess additive attributed toxicity above the overall toxicity of tobacco products, which can associate assay outcomes to human risk and exposure. In this respect, *in vitro* tests combined with

## Tobacco Additives II

---

toxicogenomics using biomarkers of exposure and disease are the most promising (Kienhuis *et al.*, 2016). However, for the time being, no standardised methods have been validated to this purpose.

Another problem with comparative testing is the choice of the product to be tested, since the additional toxicity of the additive would differ between product types and brands. If an additive would be tested in the intended brand, the results (related to toxicity, addictiveness and attractiveness) could not necessarily be generalised to all products and brands, having a different composition. Therefore the obtained results may not lead to general prohibition/acceptance of specific additives but rather to prohibition/acceptance on a product-by-product basis (DKFZ, 2010).

When the addition of sugars is taken as an example, it will be very important whether a reference containing Burley tobacco, that does not contain natural sugars, or Virginia tobacco, with high sugar levels, is selected, or a blend of these tobacco types. This is even more important as cultural differences exist in the preference for Virginia-type cigarettes, American blend, or Burley. According to the TPD, the use of additives necessary for the manufacture of tobacco products should be allowed, as long as they do not result in a characterising flavour or increase the addictiveness, toxicity or CMR properties of the product. Thus, in this particular case, sugar addition to replace what is lost during the curing process, needs to be evaluated against the possibility of toxic and carcinogenic compounds forming following pyrolysis.

For similar reasons, comparative studies are also not endorsed to study the effect of additives on addictiveness and inhalation facilitation.

Instead of using a comparative study design, the effects of the pure additive, and its pyrolysis products, must be considered in a relevant testing strategy, such as the tiered approach proposed by DKFZ (DKFZ, 2010), which has been adapted by SCHEER (Fig.1).

### 2.4.3.2 The use of animal testing

So far, available inhalation or other animal studies have been used to assess the effect of tobacco additives. However, it is ethically questionable to use animal studies to evaluate the 'safety' of a tobacco additive, as tobacco products are highly harmful with no benefits to individual or public health. Therefore, as a principle, only *in silico* and *in vitro* studies will be considered, following the EU policy recommending implementation of 3R methods for refinement, reduction, and replacement of animal models leading to the ban of animal studies for chemicals to be used in voluntary products such as cosmetics (EU Regulation no. 1223/2009). Human studies are discouraged, although they may be used in case of flavour assessment, but only if the study subjects are not exposed to the harmful smoke emissions of tobacco products. Generally and especially in those specific cases in which animals are proposed, early consultations are recommended between Receiving Competent Authorities at Member State level and tobacco industry, presenting a testing strategy including *in silico*, *in vitro* and only in exceptional cases *in vivo* tests. In order to limit the testing formation of Consortia is recommended.

Whenever animal testing should be deemed necessary, it is compulsory to be compliant with the Animal Welfare EU policy and to respect the Regulation on Animal Testing.

### 2.4.3.3 Quality system

In line with the provisions of other regulatory contexts, the SC recommends the use of a Quality system (e.g. Good Laboratory Practice or ISO17025) for carrying out the pyrolysis or other physico-chemical studies as well as toxicity studies (including those to assess the mechanism underlying possible contribution to addictiveness and attractiveness).

In case the principle of the Mutual Acceptance of Data is applied (again to limit the testing) the quality system of choice should be the GLP, following the application of the GLP OECD principles, to which all the National Monitoring Authorities in the different OECD Member States make reference. However, for the physico-chemical studies GLP compliance is not always requested and the ISO17025 could be chosen.

### 2.4.3.4 Toxicity testing

#### **In silico**

If toxicological data on the additives are not available or are limited, they can be produced using *in silico* approaches. As a first step, QSAR methods are encouraged to identify alerts for genotoxicity, carcinogenicity and reproductive toxicity, to get information of potential CMR properties of the additive or of its identified pyrolysis products: this could also take advantage of similarities with other chemicals by applying the read-across methodology.

Non-test information about the biological activity of a substance can be derived in a variety of ways, ranging from simple inspection of the chemical structure through various read-across techniques, the use of expert systems, metabolic simulators, to global or local (Q)SARs. The usefulness of such techniques varies with the amount and nature of information available, as well as with the specific regulatory questions under consideration.

Models for the identification for alert of genotoxicity and carcinogenicity have a long tradition; (Q)SAR models for mutagenicity can apply to a limited set of congeneric substances (local models) or to a wide variety of non-congeneric substances (global models).

Many global models for mutagenicity are commercial and some of the suppliers of these global models consider the data in their modelling sets to be proprietary. Proprietary means that the training set data used to develop the (Q)SAR model is hidden from the user. In other cases it means that it may not be distributed beyond use by regulatory authorities.

There are hundreds of (Q)SAR models available in the literature for predicting test results for genotoxic endpoints for closely related structures (Naven *et al.*, 2012; Bakhtyari *et al.*, 2013). These are known as local (Q)SARs. However, quality of reporting varies from model to model and predictivity must be assessed case-by-case on the basis of clear documentation.

In case of robust data on the identification of structural alert or based on read across indication of CMR properties, it is not necessary to go further, since according to the TPD no CMR substance can be used as a tobacco additive. In case there are doubts, *in vitro* testing can be conducted (see below).

## Tobacco Additives II

Regarding the other toxicological properties, other QSAR tools are available. Some of them are briefly described in the following:

OECD built an open software application (<http://www.qsartoolbox.org/>), named QSAR Toolbox. The Toolbox and guidance on its use are freely available. The OECD QSAR Toolbox facilitates the practical application of grouping and read-across approaches to fill gaps in (eco-)toxicity data, including but not limited to genotoxicity and carcinogenicity, for chemical hazard assessment. The Toolbox incorporates information and tools from various sources, into a logical workflow. Crucial characteristic of the workflow is the grouping of chemicals into categories (group of chemicals whose physicochemical and human health and/or ecotoxicological properties and/or environmental fate properties are likely to be similar or follow a regular pattern, usually as a result of structural similarity). The most important features are:

1. Identification of relevant structural characteristics and potential mechanisms or mode of action of a target chemical.
2. Identification of other chemicals that have the same structural characteristics and/or mechanism or mode of action.
3. Use of existing experimental data to fill the data gap(s).

The Joint Research Centre of the EU provides several tools for modelling for the safety assessment of chemicals. They offer the following computational tools (freely downloadable or accessible from their webpages):

- JRC QSAR Model Database: database hosting structured and peer-reviewed information on QSAR Models (<https://eurl-ecvam.jrc.ec.europa.eu/databases/jrc-qsar-model-database>);
- Toxtree, software tool to generate prediction(s) on mechanisms of action or toxicological effects, the tool is based on a decision-tree approaches ([https://eurl-ecvam.jrc.ec.europa.eu/laboratories-research/predictive\\_toxicology/qsar\\_tools/toxtree](https://eurl-ecvam.jrc.ec.europa.eu/laboratories-research/predictive_toxicology/qsar_tools/toxtree));
- Dart, (Decision Analysis by Ranking Techniques) a software tool designed to rank chemicals according to environmental and toxicological concerns ([https://eurl-ecvam.jrc.ec.europa.eu/laboratories-research/predictive\\_toxicology/qsar\\_tools/DART](https://eurl-ecvam.jrc.ec.europa.eu/laboratories-research/predictive_toxicology/qsar_tools/DART));
- Toxmatch, a flexible application for grouping chemicals based on chemical similarity designed to be helpful in read-across ([https://eurl-ecvam.jrc.ec.europa.eu/laboratories-research/predictive\\_toxicology/qsar\\_tools/toxmatch](https://eurl-ecvam.jrc.ec.europa.eu/laboratories-research/predictive_toxicology/qsar_tools/toxmatch)).
- Stat4tox, a tool which carries out concentration-response analysis for *in vitro* experiments ([https://eurl-ecvam.jrc.ec.europa.eu/laboratories-research/predictive\\_toxicology/qsar\\_tools/stat4tox](https://eurl-ecvam.jrc.ec.europa.eu/laboratories-research/predictive_toxicology/qsar_tools/stat4tox)).

ECHA provides a detailed overview on non-testing methods in sub-section R.7.7.3.1 of Guidance on Information Requirements and Chemical Safety Assessment Chapter R.7a: Endpoint specific guidance (see [http://echa.europa.eu/documents/10162/13632/information\\_requirements\\_r7a\\_en.pdf](http://echa.europa.eu/documents/10162/13632/information_requirements_r7a_en.pdf)), in particular with regard to the prediction models for mutagenicity and the OECD QSAR toolbox.

## Tobacco Additives II

A list of the available (free and commercial) predictive software for ecotoxicological, toxicological and environmental endpoints, including mutagenicity models, has been compiled within the frame of the EU project Antares (<http://www.antares-life.eu/>). For example, the Danish EPA and the Danish QSAR group at DTU Food (National Food Institute at the Technical University of Denmark) have developed a (Q)SAR database that contains predictions from a number of mutagenicity models. The database is freely accessible via <http://qsar.food.dtu.dk>. The online database contains predictions for over 166,000 substances and includes a flexible system for chemical structure and parameter searching. A user manual with information on the individual models including training set information and validation results is available at the website. The database is also integrated into the OECD (Q)SAR Toolbox.

Another example of a database with predictions on mutagenicity is the Enhanced NCI Database Browser (<http://cactus.nci.nih.gov>) sponsored by the U.S. National Cancer Institute. It contains predictions for over 250,000 substances for mutagenicity as well as other nonmutagenic endpoints, some of which may provide valuable mechanistic information (for example alkylating ability or microtubule formation inhibition). It is also searchable by a wide range of parameters and structure combinations.

Use of harmonised templates, such as the QSAR Model Reporting Format (QMRF) and the QSAR Prediction Reporting Format (QPRF) developed by the Joint Research Centre (JRC) of the European Commission ([http://ihcp.jrc.ec.europa.eu/our\\_labs/predictive\\_toxicology/qsar\\_tools/QRF](http://ihcp.jrc.ec.europa.eu/our_labs/predictive_toxicology/qsar_tools/QRF)), can help to ensure consistency in summarising and reporting key information on (Q)SAR models and substance specific predictions generated by (Q)SAR models. The JRC website also hosts the JRC (Q)SAR Model Inventory, which is an inventory of information on the validity of (Q)SAR models that have been submitted to the JRC ([http://ihcp.jrc.ec.europa.eu/our\\_databases/jrc-qsarinventory](http://ihcp.jrc.ec.europa.eu/our_databases/jrc-qsarinventory)).

If the exposure could be well characterised without uncertainties, the application of the Threshold of Toxicological Concern (TTC) concept could be foreseen in the future, when the applicability domain will be expanded to include the inhalation route in the data base.

### **In vitro**

There are a number of *in vitro* tests that can be used to assess many different toxicological end-points. *In vitro* toxicity tests are applicable to a wide variety of test materials including ingredients added to tobacco, tobacco extracts, tobacco smoke condensates, and whole or vapour phase smoke. These assays may also be used to explore interactions between components of cigarette smoke.

The first choice has to be given to tests already adopted at international levels (e.g. OECD Test Guidelines<sup>14</sup>, or ISO methods) or tests validated by ECVAM. The OECD test guidelines (TGs) describe the applicability domain, the principles of methods and the procedure and they also address reporting.

In case a non-TG *in vitro* method is used (e.g. a test validated by ECVAM), the reporting should be appropriate, following what it is indicated in the OECD Guidance Document for

<sup>14</sup> <http://www.oecd.org/chemicalsafety/testing/oecdguidelinesforthetestingofchemicals.htm>

## Tobacco Additives II

describing Non-Guideline *in vitro* test methods No.211 (2014)<sup>15</sup>. The application of integrated approaches on testing and assessment (IATA) is highly recommended, as described in documents adopted by both ECVAM and OECD<sup>16</sup>.

Since the acceptance at regulatory levels is evolving, the TG as well as the GDs are revised periodically, therefore it is compulsory that in choosing the appropriate test, the tobacco industry follows the most updated version. Indeed, as requested by EU regulation 1223/2009 on cosmetics, the EU Commission has to report every year to European Parliament as well as to the EU Council on the progress related to the development, validation and regulatory acceptance of alternative methods as communicated by a Report from EURL-ECVAM<sup>17</sup>.

If information gathered through *in silico* methods are not conclusive and there are doubts related to genotoxicity potential, an *in vitro* genotoxicity test battery or *in vitro* transformation test for carcinogenicity can be applied to clarify these end-points. The *in vitro* genotoxicity testing methodologies are well described in the several adopted OECD TG:

- 471: Bacterial Reverse mutation, 1997
- 473: *In vitro* mammalian Chromosomal Aberration Test, 2014 Rev
- 476: *In vitro* Mammalian Cell Gene Mutation Test, 1997, 2015 Rev
- 479: *In vitro* SCE Assay in mammalian cells, 1986
- 480: *S. cerevisiae*, gene mutation assay, 1986
- 481: *S. cerevisiae*, Mitotic Rec. assay, 1986
- 482: DNA damage and Repair, UDS in mammalian Cells *in vitro*, 86
- 487: *In vitro* Mammalian cells Micronucleus test, 2014 Rev
- 490: *In vitro* Mammalian Cell Gene Mutation Tests Using the Thymidine Kinase Gene, 2015

In the battery, it would be necessary to include tests able to identify point mutations in prokaryotic and mammalian cells as well as chromosomal aberrations and DNA damage and repair.

*In vitro* methods to address local toxicity (i.e. phototoxicity, skin corrosion and irritation, eye irritation, skin sensitisation) are available (see table 1) and should be performed using the air-liquid interface.

More difficult is to address systemic toxicity by means of *in vitro* testing only, since at the moment no adopted TGs are available.

For carcinogenicity, two cell transformation assays have been included in OECD guidance Documents (table 1), which - using an IATA with *in silico* and read across data - could give sufficiently robust information.

## Tobacco Additives II

Only a few *in vitro* studies are available to address very specific reactions possibly leading to reproductive problems, such as *in vitro* binding to estrogen and androgen receptors (see the OECD conceptual framework to evaluate endocrine disrupting chemicals). Nevertheless, they can be included, and evaluation should be carried out also considering the indication coming from QSAR and read across.

Cytotoxicity testing after repeated exposure (e.g. 14 days) is considered a possible end-point of choice (acute toxicity is not relevant for tobacco products, hence also for additives). Positive and negative controls should be used, cells of human origin have to be preferred; non-specific tests as well as organ specific cells should be used (e.g. cells coming from the lung or intestinal cells, accounting for inhalation and swallowing of smoke, but also cells representing CNS, cardiovascular system, etc. to be evaluated on a case-by-case basis). For a correct interpretation of results it should be considered that whenever cell lines are used, they are generally characterised by a low and unbalanced metabolic capability, therefore at least one of them should maintain this function over the treatment period (e.g. HepaRG cells) or primary cells should be used.

The major endpoints evaluated in *in vitro* cytotoxicity assays include the effect of a substance on cell viability (survival) and growth rates, but other end-points (such as mitochondrial functionality, induction of apoptosis) can be included. Cytotoxicity testing is used in the area of medical devices: methods to be considered can be found within the harmonised European standard ISO 10993-1:2009 "Biological evaluation of medical devices Part 1: Evaluation and testing within a risk management process". The ISO 10993 – 5:2009 describes test methods to assess the *in vitro* cytotoxicity of medical devices.

However, the study design should take into account that the most relevant route of exposure for tobacco additives is inhalation.

There has been significant progress made in recent years in approaches to expose cells *in vitro* to chemicals that pose a toxicological concern via the inhalation route (Aufderheide *et al.*, 2011; Bakand and Hayes, 2010). A number of *in vitro* exposure systems have been developed to facilitate the study of the effects of the whole smoke mixture on both mammalian and bacterial cells, and this has been the subject of a recent review (Thorne and Adamson, 2013).

Current cell-based *in vitro* models of the respiratory tract consist mainly of 2D monolayers of primary tracheobronchial epithelial cells or an immortalized cell line cultured on a semipermeable membrane insert at an air-liquid interface to induce cell polarization, differentiation, and mucus production (Forbes *et al.*, 2005). A more sophisticated technique that enables the stable and reproducible exposure of cultivated cells to cigarette smoke at the air-liquid interface such as CULTEXW Radial Flow System (RFS) module has been proposed recently (Rach *et al.*, 2013).

It was documented that air-liquid interface culture played a significant role toward the *in vitro* recapitulation of the *in vivo* environment, presenting the cells with an apical side resembling the lumen of the respiratory tract and a basolateral side representing vascular supply of nutrients, (Berube *et al.*, 2010) with increased expression of cilia in primary cells and differences in barrier and mucus-secreting properties of cell lines observed (de Jong *et al.*, 1994, Grainger *et al.*, 2006). However, the absence of an extracellular component with cocultured cells in a 3D environment can result in an oversimplification of the airway barrier, lacking in physiological relevance. Therefore, more sophisticated models based on 3D human normal and diseased tissue are required

## Tobacco Additives II

to provide *in vitro* models that improve validity of tested compounds in humans. Much of respiratory tissue engineering research has seen a transition from single cell-type culture on inserts toward co-culture and the inclusion of scaffold material. Accordingly, models, in which the epithelium is cultured at an air-liquid interface over a scaffold substrate embedded with cocultured cells, are the subject of much interest and are even available now as commercial 3D research products, such as the MatTek EpiAirway-FT technology (Berube *et al.*, 2010). Indeed, there is an overall consensus in the literature that introducing an epithelial cell analogue into the co-culture environment, often through the use of a biomaterial scaffold, could enhance cell culture, cell-cell signalling, and functionality. A triple coculture system in which human bronchial epithelial cells A 549, human mesenchymal cells and dendritic cells were cultured in monolayers, has shown promise for studying immunological responses to inhaled particulates (Rothen-Rutishauser *et al.*, 2005, Herzog *et al.*, 2013). Co-culture of Calu-3 cells with Wi38 lung fibroblasts was achieved on the scaffold to create a submucosal tissue analogue of the upper respiratory tract, validating system as a platform to support co-culture and cellular organisation reminiscent of *in vivo* tissue architecture. These scaffolds were validated as a substrate to support functional mucus express from an airway epithelium. Calu-3 cells cultured on CHyA-B scaffolds also expressed the tight junction protein ZO-1 and F-actin, indicating the formation of an epithelial barrier layer on the constructs and differentiation of the Calu-3 cells. Recently, another *in vitro* model system using tissue-engineered constructs has been developed which might improve our understanding of epithelial tissue and disease and use for testing toxicity of different compounds (O'Leary *et al.*, 2016).

Tobacco smoke assessment *in vitro* has traditionally focused on the particulate phase captured on a Cambridge filter pad and eluted in DMSO (Crooks *et al.*, 2013) or bubbled through cell culture media or PBS (Andreoli *et al.*, 2003). Cell cultures are then exposed under submerged conditions to the particulate phase. Unfortunately, particulate-based exposure scenarios do not take into account the vapour phase of cigarette smoke, or the associated interactions between the particulate and vapour phases.

Submerged culture conditions and particulate-based exposures do not represent physiologically that of mainstream tobacco smoke exposure in the human lung. Furthermore, separating smoke fractions in this way could lead to alterations and chemical changes that may not be representative of the whole smoke aerosol. In order to address these challenges, whole smoke exposure systems have been developed. Whole smoke exposure systems offer many technical challenges, but represent a more physiologically relevant test system that captures the full interactions of both the particulate and vapour phases together (Fukano *et al.*, 2004). An additional advantage of these systems is that a multitude of different cell cultures can be exposed at the air-liquid interface (ALI) to whole smoke, better simulating human exposure (CORESTA, 2007).

Whole smoke exposure systems offer the advantage that all phases of smoke can be analysed together or independently depending on the experimental set-up. This has allowed researchers to tailor their experiments to investigate both phases of tobacco smoke, yielding useful information. There is a variety of whole smoke systems available and the majority of these systems can also be used to deliver individual aerosols or other complex aerosol mixtures to cell cultures. However, at present there is no recognised approach to the measurement of dose, and the vapour phase of cigarette smoke within these systems remains poorly understood. With the variety of exposure

## Tobacco Additives II

options available to researchers and bespoke systems relatively easy to fabricate or replicate, dosimetry tools may bridge the gap and play an important role, not only in the measurement of actual cellular dose but also in the characterisation and validation of these systems (Thorne and Adamson, 2013).

There are continuous efforts to introduce existing testing methods into regulatory framework of tobacco products risk assessment.

The Cooperation Centre for Scientific Research Relative to Tobacco (CORESTA, 2004) *in vitro* Toxicology Taskforce of industry recommends using a test battery composed of the following assays:

1. A bacterial mutagenicity assay. The Ames Salmonella mutagenicity assay is recommended.

2. A mammalian cell assay for cytogenetics/mutation. The Task Force recommends the micronucleus assay, the chromosome aberration assay or the L5178Y mouse lymphoma assay.

3. A cytotoxicity assay conducted with an appropriate mammalian cell line. The Task Force recommends the neutral red cytotoxicity assay (CORESTA, 2004).

Analysis of the recent publication has shown that these recommendations are used increasingly in the toxicity assessment of different tobacco products (see e.g. Manupallo and Sullivan, 2015).

Considering non-cancer endpoints, a battery of *in vitro* tests have been proposed for assessing CVD risk associated with cigarette smoking (Fearon *et al.*, 2013). The battery is comprised of functional *in vitro* assays to model endothelial damage, angiogenesis, and migration of vascular smooth muscle cells as initial and subsequent events in CVD (Fearon *et al.*, 2013). Other tests, such as for oxidative stress or inflammatory response, may be conducted to assess the adverse effects of cigarette smoke *in vitro*.

However, it is the opinion of SCHEER that the choice of the test battery should not be fixed *a priori*, and should be rather tailored on the basis of information coming from the *in silico* and read-across analysis (e.g. bridging *in vitro* studies can be necessary to support the read across).

Table 1 summarises the most recent, internationally accepted, validated *in vitro* methods, which may be used for the toxicity assessment of the tobacco products.

Modified after AltTox (<http://alttox.org/mapp/table-of-validated-and-accepted-alternative-methods>) and PISC ([http://www.piscitd.org.uk/wp-content/uploads/2016/03/PISC\\_AltMethods\\_A4](http://www.piscitd.org.uk/wp-content/uploads/2016/03/PISC_AltMethods_A4))

2

Besides these internationally validated methods and the ISO 10993 – 5:2009 adopted for medical devices, there is a great number of other methods employing technological innovations such as reconstituted human tissue cultures, 3-D organotypic cultures comprised of differentiated human cells in co-cultures, air-liquid interface exposure systems, cell transformation assays and high content genomic analysis that are used for tobacco product analysis.

#### 2.4.3.5 Addictiveness testing

Tobacco comprises of thousands of substances, of which nicotine is the most characterising and most addictive component. Additives, as well as natural tobacco substances other than nicotine, may have addictive capacities themselves or can interact with nicotine and the nicotine receptor system, herewith enhancing the effects of nicotine. For example, these additives can have effects on nicotine bioavailability, duration, and concentration in the blood circulation or nicotine-dependent activation of mesolimbic pathways in the brain. The term 'dependence potential' is commonly used to describe addictive capacity.

Guidelines to assess the impact of tobacco product contents on dependence potential could be similar to those already established for testing the dependence potential of pharmaceutical products (the used methods are known as Abuse Liability Assessment). Special challenges include product complexity and the diverse range of tobacco products (Henningfield *et al.*, 2011; WHO Study Group on Tobacco Product Regulation TobReg, 2012). For example, the US FDA has issued guidance that covers dependence potential assessment for a range of different substances, formulations, and product types in which factors such as additives and product design features may act to either promote or deter dependence potential (U.S. Dept. of Health and Human Services, 2010, 2015).

Experimental testing of the dependence potential of tobacco additives is still limited due to the lack of validated administration models for the examined individual compound itself and in co-administration with other tobacco additives. In the proposed step-wise approach, we discuss the possibilities to experimentally quantify the dependence potential of tobacco additives (often) co-administered with nicotine.

#### **In silico**

**Nicotinic acetylcholine receptor (nAChR) Computer models.** nAChRs are ligand-gated cation channels found throughout the central and peripheral nervous systems (Gotti *et al.*, 2006; Jensen *et al.*, 2005). Neuronal nACh receptors participate in many neurological processes including cognition (Levin and Simon, 1998), pain sensation (Damaj *et al.*, 2000), and nicotine reward/addiction mechanisms (Dani and De Biasi, 2001; Pavlovicz *et al.*, 2011; Tapper *et al.*, 2004). In the past years several nAChR *in silico* models have been developed integrating protein (sub-) structures, dynamics and functional relationships. Among those, the most widely expressed nAChR subtype in the brain is the neuronal  $\alpha 4\beta 2$  nACh receptor (Haddadian *et al.*, 2008). The  $\alpha 4\beta 2$  nAChR comprises high-affinity nicotine-binding sites (Tapper *et al.*, 2004) but the mechanism how ligand binding leads to channel opening remains elusive. The quality of the current  $\alpha 4\beta 2$  nAChR model was evaluated using flexible docking of nicotine docking to the closed- and open-channel models. Besides the potential nicotine interactions with surrounding residues that could stabilize nicotine positions, a high degree of involvement of aromatic residues in the nicotine binding sites was also observed (Haddadian *et al.*, 2008). Further development of these models may provide information about how

nicotine and other tobacco additives (ligands) regulate nAChR activation in smoking dependence.

**Ligand-based Monoamine oxidase (MAO) models.** The enzyme MAO plays an important role in the metabolism of several neurotransmitters by oxidative deamination. MAO-A inhibition is associated with enhanced dopamine activity leading to increased reinforcement behaviour. The combustion of natural or added sugars in tobacco products result in acetaldehyde which reacts in the body with tryptophan and tryptamine. This reaction results in the formation of the beta-carbolines, harman and norharmane, which are MAO inhibitors (Herraiz and Chaparro, 2005; Talhout *et al.*, 2007). Other examples of MAO inhibitors isolated from tobacco leaves or present in tobacco smoke are 2,3,6-trimethyl-benzoquinone, 2-naphthylamine and a coffee-extracts and synthesized and modified natural coumarin derivatives (Fowler *et al.*, 2003; Gnerre *et al.*, 2000; He *et al.*, 2014; Herraiz and Chaparro, 2006).

Ligand-based models can provide new insights in enzyme selectivity, mechanisms of action and the relationship between the MAO inhibitory activity and the molecular structure of the different inhibitors (Vilar *et al.*, 2012). There are different types of ligand-based models which can be used, such as Quantitative Structure-Activity Relationship (QSAR) with 2D and 3D descriptors (Johnson, 1976; Vilar *et al.*, 2008; Winkler, 2002), 3D- Comparative Molecular Field Analysis (CoMFA) (Cramer *et al.*, 1988; Zhang *et al.*, 2011), 3D-pharmacophores (Langer and Hoffmann, 2006) or ligand-network models (Keiser *et al.*, 2007; Park and Kim, 2008). QSAR studies have become one of the most popular ligand-based approaches in modern chemistry (Shelke *et al.*, 2011; Vilar *et al.*, 2008; Vilar *et al.*, 2012) and can also be used to model ligand-based selectivity of different tobacco additives and the potency to inhibit MAO activity.

### **In vitro**

**Three-dimensional lung tissue constructs (3D lung-on-a chip) and mathematical computer models.** These kind of models are the results of the integration between *in vitro* models (the 3D organ-on-a-chip) and *in silico* models. It has been shown that inhalation during smoking results in a rapid brain increase of nicotine in the brain thereby contributing to nicotine dependence in smokers. Inhalation can be facilitated by certain additives leading to deeper and more frequent inhalation by the cigarette smoker resulting in an increase in lung exposure and nicotine uptake. Additives (e.g. menthol, theobromine and eucalyptol) can achieve this by enhancing sensory properties such as cooling effects or by having local anaesthetic and bronchodilating properties (Usmani *et al.*, 2005). Also, a change in the physical properties of tobacco (e.g. particle size) can be altered by certain additives to allow (nicotine) particles to enter deeper levels of the lungs (SCENIHR, 2010a).

The efficiency of nicotine uptake and tobacco additives via the lung in the blood stream is difficult to measure. Engineered 3D lung tissue constructs and mathematical computer models can be used to provide predictive information on lung uptake and particle deposition (Asgharian *et al.*, 2012; Nichols *et al.*, 2014; Nichols *et al.*, 2013). These engineered 3D models of human tissue mimic *in vivo* conditions and allow for more natural and robust human *in vitro* respiratory tract models compared to multi-cell *in vitro* models. These constructs can be used to assess cell-based responses, physiologic functions, pathologic changes and even toxicity or responses to tobacco additives.

The 3D lung-on-a-chip can be used also to measure experimentally effects due to any additive in **altering nicotine uptake** such as alkalizing compounds

## Tobacco Additives II

---

**Capacity to change pH values.** Additives that exert capacities to increase the pH values will result in higher amounts of uncharged nicotine (Hurt and Robertson, 1998; Wayne and Carpenter, 2009). This will result in more easily absorption of nicotine by the epithelial cells in the mouth and probably also in the lungs (Tomar and Henningfield, 1997). Although the tobacco industry stresses that the buffering capacity of the lung surface liquid (7mval/pH unit) at pH 7.4 is not changed by nicotine concentrations of 0.1 mg per puff (Holma and Hegg, 1989; Klus *et al.*, 2012), it is valuable to check additives or substances for their capacity to change the pH of the tobacco and the smoke.

**(Inhibition of) The enzymatic activity of MAO.** Additives may influence the dependence potential of nicotine by interacting with the neural responses to the drug. For example, MAO inhibitors that are not leading to dependence on their own slow the breakdown of monoamines such as DA thereby affecting the overall motivational impact of nicotine. Inhibition of the enzymatic activity of MAO can be measured *in vitro* using peroxidase-linked spectrophotometric assay. Enzymes can be isolated from rat liver microsomes or by recombinant generated enzymes. Using recombinant human MAO-A and MAO-B, IC50 values for enzyme inhibition can be experimentally determined (Lewis *et al.*, 2007). *In vivo* MAO activity can be analysed using PET (see paragraph 'neurobiological effects using imaging techniques').

**CYP metabolism inhibitor ratio.** Nicotine is metabolized in the liver by cytochrome CYP2A6 and CYP2B6 enzymes (Hukkanen *et al.*, 2005). Inhibition of nicotine metabolism enhances its bioavailability and alters the behavioural effects in mice (Alsharari *et al.*, 2014; Bagdas *et al.*, 2014). Additives modulating the activity of metabolic pathways are therefore likely to affect the dependence potential of nicotine. The effectiveness of an additive in inhibiting nicotine metabolism is expressed as relative CYP inhibitor ratio (Rahnasto *et al.*, 2008). The inhibitory concentration of human and mouse CYP2A can be tested in an *in vitro* assay using recombinant enzyme or human liver microsomal preparations (Rahnasto *et al.*, 2003). Examples of known tobacco additives that inhibit CYP2A6 enzymes are menthol, benzaldehydes and several lactones added to tobacco (Benowitz *et al.*, 2004; Kabbani, 2013; Kramlinger *et al.*, 2012; Rahnasto *et al.*, 2003).

### **In vivo (not recommended as the first choice)**

**Biomarker analysis of nicotine.** Nicotine bioavailability is defined by an optimal rate of adsorption and distribution from the lungs into the bloodstream. Upon uptake in the lungs, the bioavailability of nicotine in the body is determined by properties such as its hydrophobicity and solubility. It has been proposed that the use of alkalizing compounds (such as ammonia) as tobacco additive increases the absorption of nicotine in the lungs. A biomarker analysis of nicotine in blood samples from smokers of cigarettes with different ammonia yields was performed to evaluate the effects on nicotine bioavailability. Different ammonia yields in cigarettes did not increase the rate or amount of nicotine absorption from the lungs to the arterial blood circulation (McKinney *et al.*, 2012; van Amsterdam *et al.*, 2011). It can not be excluded from these studies that other ingredients than ammonium salts influence nicotine adsorption in a similar way.

**Dopamine (DA) release and turn over.** Activity of neurons in the mesolimbic DA brain area is not only measured by nACh receptor activation but also by measuring the result of this receptor activation, a change in the release or turnover of DA. DA release and turnover can be measured either *ex vivo* or *in vivo* via isolation of specific

## Tobacco Additives II

brain tissue or microdialysis. A study in mice showed up-regulation of nAChR subtypes in various brain regions upon exposure to nicotine and menthol using western blots. A significant increase in nicotine plasma levels was observed, which was accompanied by an increase of withdrawal intensity (Alsharari SD1, 2015).

**Neurobiological effects using imaging techniques-** Exerting additive effects on nicotine dependent activation of the mesolimbic pathway can be studied *in vivo* using several neuroimaging techniques like functional magnetic resonance imaging (fMRI), positron emission tomography (PET) and single-photon emission computed tomography (SPECT) (Jasinska *et al.*, 2014). Each technique can be used to understand only some aspects of processes involved in tobacco consumption like brain structure (MRI), different aspects of brain function (PET, SPECT, fMRI, and ASL), and pharmacokinetics (PET, SPECT) in animals as well as humans (Kober and Deleone, 2011).

The neuronal activity upon exposure to nicotine and other tobacco additives can be measured by the activation of nACh receptors, neurotransmitter release and transcriptional activation of specific mRNAs (van de Nobelen *et al.*, 2016). Labelling and tracing of nicotine, MAO or nAChR can demonstrate nicotine occupancy at nAChRs, nAChR availability and upregulation of nAChRs induced by tobacco smoking (Brody *et al.*, 2014; Jasinska *et al.*, 2014; Volkow *et al.*, 1999). Substances that inhibit the nicotine degradation or metabolism or serve as a carrier for nicotine can be identified by these derivative endpoints.

PET- is a common functional neuroimaging technique which uses a short-lived radioactive tracer (incorporated into a biologically active molecule as glucose) infused into a living subject. As the tracer decays, the PET system detects pairs of gamma rays that are indirectly emitted in the process, and uses them to localize the tracer to a particular region in the brain. In this way, the concentration of tracer molecules can be estimated at different locations in the brain or other tissue. Several tracers are discussed below.

**Radiotracer for nicotine-** A PET study with radiolabelled nicotine [ $^{11}\text{C}$ ]nicotine demonstrated that a single puff leads to a rapid rise in brain nicotine concentration with a gradual wash-out period (Berridge *et al.*, 2010). In addition, the nicotine accumulation in the brain during smoking of one full cigarette increases in a linear fashion with successive puffs, rather than in puff-associated spikes and rapid wash-outs. Relating to this finding, the authors reported that dependent smokers showed a slower rate of brain nicotine accumulation than non-dependent smokers (Kober and Deleone, 2011; Rose *et al.*, 2010).

**Radiotracers for  $\alpha 4\beta 2$ \*nACh receptors-** Researchers have also developed brain-imaging radiotracers for  $\alpha 4\beta 2$ \*nACh receptors with radiolabelled A-85380 compounds (Abreo *et al.*, 1996) or analogues (2-FA /6-FA for PET and 5-IA for SPECT), having the most widespread use (Koren *et al.*, 1998). However, the slow kinetics of these radio ligands restricts the large-scale use in experimental studies (Sabri *et al.*, 2015). New generation  $\alpha 4\beta 2$ \*nAChR specific radioligands are now under development, like [18F]Flubatine, [18F]AZAN and [18F]nifene, demonstrating faster kinetic properties in PET research (Brust *et al.*, 2008; Hillmer *et al.*, 2011; Hockley *et al.*, 2013; Kuwabara *et al.*, 2012; Wong *et al.*, 2013).

PET imaging studies demonstrated the effect of cigarette smoking on  $\alpha 4\beta 2$ \*nAChR occupancy, showing that smoking causes displacement of 2-FA for prolonged time (at least several hours) (Brody *et al.*, 2006a). Dose-dependent reduction in 2-FA

displacement was observed by both controlling the number of puffs smoked and the nicotine concentration smoked (Brody *et al.*, 2009). These findings suggest that nicotine mediates 2-FA displacement by occupying  $\alpha 4\beta 2^*$  nAChRs. Several authors, using 5IA-SPECT and 2-FA-PET, have shown that habitual cigarette smoking is associated with up-regulation of  $\alpha 4\beta 2^*$  nAChRs (Cosgrove *et al.*, 2009; Mamede *et al.*, 2007; Mukhin *et al.*, 2008; Staley *et al.*, 2006; Wullner *et al.*, 2008). The nAChR density returns to normal after a prolonged abstinence of weeks to months (Cosgrove *et al.*, 2009; Mamede *et al.*, 2007). In addition, exposure to nicotine from second-hand smoke resulted in substantial brain  $\alpha 4\beta 2^*$ nAChR occupancy in smokers and non-smokers (Brody *et al.*, 2011). Taken together, these results suggest that exposure to cigarette smoke, most likely through the effects of nicotine, influences  $\alpha 4\beta 2^*$ nAChR density in the human brain (Lotfipour *et al.*, 2011).

**Radiotracer for Dopaminereceptor (DA)-** With radiotracers such as [<sup>11</sup>C]raclopride and [<sup>11</sup>C]PHNO (PET) or [<sup>123</sup>I]IBZM (SPECT), striatal DA release has been reliably measured using PET and SPECT imaging (Laruelle, 2000). An increase in DA competes with the radiotracer to bind at the dopamine receptor; resulting in a decrease in radiotracer binding compared to baseline. This allows calculation of the 'occupancy' of the receptors by DA or a change in binding potential and is an indirect measure of DA release based on the 'occupancy model' (Cosgrove *et al.*, 2015; Laruelle, 2000).

Many studies have examined nicotine and tobacco smoking-induced DA release in human subjects. All these studies confirm that smoking elicits ventral striatal dopamine release and is associated with a reduction of craving (Barrett *et al.*, 2004; Brody *et al.*, 2006b; Brody *et al.*, 2004; Montgomery *et al.*, 2007; Scott *et al.*, 2007; Takahashi *et al.*, 2008). In the most recent study, smokers were imaged with [<sup>11</sup>C] PHNO before and after a cigarette (Le Foll *et al.*, 2014). Binding potential was reduced after smoking by 12 and 15 % in D2-rich and D3-rich regions, respectively.

A major concern with the existing studies is the timing of the dopamine response. The response to smoking a cigarette is a transient increase in DA. The analysis in these studies, however, use an average of all the data collected over 30 min to up to 2 h. This significantly dilutes measurement of a transient dopamine response (Sullivan *et al.*, 2013). Thus, analysis techniques with improved temporal resolution may be better suited to more transient DA release (Cosgrove *et al.*, 2015).

**Radiotracers for  $\mu$ -opioid receptors-** There is strong evidence for a link between nicotine administration and endogenous  $\mu$ -opioid mechanisms, mediating some of nicotine's addictive properties and distress during withdrawal (Nuechterlein *et al.*, 2016). Acute endogenous opioid release upon nicotine administration was demonstrated in animal and cell culture studies (Boyadjieva and Sarkar, 1997; Davenport *et al.*, 1990). However, in human studies the findings are inconsistent. The indirect measures of neurotransmitter release and  $\mu$ -opioid receptor activation upon nicotine administration, as measured with PET, have shown both a reduction in binding potential (suggesting activation of neurotransmission) and an increase in binding potential (deactivation) or no significant change in different regions of the brain (Domino *et al.*, 2015; Kuwabara *et al.*, 2014; Ray *et al.*, 2011; Scott *et al.*, 2007). Measures at baseline have also shown either lower or no significant differences between smokers and non-smoking controls (Kuwabara *et al.*, 2014; Scott *et al.*, 2007). The  $\mu$ -opioid system is suggested to be strongly influenced to placebo treatment (Nuechterlein *et al.*, 2016; Pecina *et al.*, 2015; Scott *et al.*, 2008; Zubieta *et al.*, 2005). Therefore, studying the opioid system does not seem the most sensitive and robust way to define tobacco dependence.

## Tobacco Additives II

How the administration of tobacco additives changes these effects as measured is largely unknown. A recent PET study showed that in brains of female menthol cigarette smokers, nicotine accumulated faster thereby contributing to dependence. However a role of menthol in enhancing brain nicotine accumulation was not supported by this study (Zuo *et al.*, 2014). Another PET study using labelled nAChR subunits showed an upregulation of these receptors in the brain of menthol smokers, indicating a higher nicotine exposure in smokers of menthol cigarettes (Brody *et al.*, 2013). However, other mechanisms for menthol-influencing receptor density are possible. Analysis of nicotinic acetylcholine receptor activity *in vitro* shows that menthol inhibits nAChR subtypes in a non-competitive manner (Ashoor *et al.*, 2013; Hans *et al.*, 2012).

**SPECT-** In SPECT the same mechanism is used as in PET, but differs in a way that the radioactive tracer directly emits a single gamma ray during decay. The nature of the signal allows for lower resolution images than PET as the SPECT tracers typically have a longer half-life, but scans are more easily performed. There are differences in the physics and chemistry used in PET versus SPECT, but the outcome measure of receptor availability is the same. Depending on the tracer used, PET and SPECT data can quantify regional brain activity (e.g. via glucose metabolism when the tracer is a modified sugar, as in 18F-fluorodeoxyglucose), receptor occupancy (e.g. with 11C-raclopride and dopamine receptors), and pharmacokinetics when multiple measurements are taken after drug consumption.

**Functional Magnetic Resonance Imaging (fMRI)-** Besides PET, which is already advanced technique in this field of research, fMRI is a promising and non-invasive upcoming technique. In fMRI, blood oxygen levels (brain activity) can be measured in the brain by use of strong magnetic fields. In the first fMRI study on the effect of acute nicotine administration, active smoking participants were injected with nicotine in different concentrations. A dose- and time-dependent increased BOLD signal occurred in several cortical and subcortical regions, with prominent signal changes in the cingulate cortex, dorsolateral and medial orbitofrontal regions (Stein *et al.*, 1998) as well as the ventral striatum, amygdala, thalamus and insula (Menossi *et al.*, 2013). fMRI studies assessing tobacco additives with a (passive) inhalation tobacco devices can be used to identify brain areas involved in addiction. As there are no validated administration models for smoking or nicotine administration which can be used during scanning this is an important limiting factor in fMRI research.

The majority of the above-mentioned imaging studies focus on chronic exposure in a cross sectional design (smokers vs. non-smokers) at a single point in time. When focusing on the dependence capacity of tobacco additives, studies on acute effects using within subject measurements (placebo vs. additive(s) of interest) is regarded as more valuable. This will improve the sensitivity to picking up small changes in neuronal activity caused by administration of the additive. Repeated exposure and repeated measurements can predict dependence capacity. Further improvement of the study protocol and development of even more efficient radio ligands may be beneficial to find indications for tobacco additives that increase dependence.

**Behavioural responses in rodents.** Current animal models for tobacco product dependence are based on assessing nicotine dependence rather than dependence of tobacco additives or tobacco products as a whole. These models aim to deliver pure nicotine using an intravenous self-administration paradigm despite the fact that nicotine itself is regarded as a relatively weak reinforcer (Caille *et al.*, 2012). Current tests to analyse dependence potential can monitor self-administration, speed of acquisition,

## Tobacco Additives II

---

conditioned rewarding effects and drug discrimination (Hoffman and Evans, 2013; Wilkinson and Bevins, 2008; Yasarbas *et al.*, 2010). Also severity of withdrawal can be measured (Bagdas *et al.*, 2014). Animal models also allow controlling of factors that can affect study outcome such as environmental factors, genetic background and prior drug exposure. The self-administration paradigm has been widely accepted as a reliable animal model with high predictive value for the dependence potential of a drug and can be used to support findings observed in humans. The current available models can possibly be adapted to assess the effect of (nicotine in combination with) other tobacco-related additives on dependence. A recent animal study showed that the sensory properties of menthol can serve as a conditioned reinforcer for nicotine (Wang *et al.*, 2014).

**Behavioural outcome measures in human.** Several behavioural measures can be used to assess dependence in human. Dependence for nicotine and smoke(less) tobacco can be self-assessed using the Fagerström Test for Nicotine Dependence (FTND) or the cigarette withdrawal scale (CWS-21) (Etter, 2005; Etter *et al.*, 2003; Fagerstrom, 2012). The FTND uses a twelve-item cigarette dependence scale that covers the main definitions of dependence: compulsion, withdrawal symptoms, loss of control, neglect of other activities, time allocation and persistence despite harm. The FTND can assess the degree or severity of tobacco dependence using a scale indicative for the level of dependence.

The cigarette withdrawal scale (CWS-21) is a 21-item multidimensional self-administered scale that measures withdrawal symptoms and predicts relapse to smoking (Etter, 2005). Recently, a revision for DSM-V was proposed in order to increase the predictive value of these criteria for tobacco dependence assessment (American Psychiatric Association, 2013; Baker *et al.*, 2012).

Indicators of nicotine dependence were assessed in menthol and non-menthol cigarette smokers using the FTND. Differences were observed in time to first cigarette of the day (TTF) suggesting greater urgency to smoke but not on amount of cigarettes smoked on a day (CPD) (Collins and Moolchan, 2006; Hoffman and Simmons, 2011). An important limitation of these methods is that these tests are a diagnostic instrument for assessing dependence in people and not necessarily the dependence potential of the given substance or product type.

### **Recommendations**

To accurately assess tobacco dependence potential for regulatory purposes, it is necessary to use multiple evaluation methods, whereby several factors associated with tobacco dependence are analysed. Combinations of techniques examining neurochemical physiological and behavioural changes in specific brain regions with nicotine dependence will provide sufficient and robust information. Correlations between responses and convergence of studies will lead to evidence-based conclusions. For regulatory purposes, consensus needs to be established on the (combination of) tests that are preferred. The SCHEER therefore proposes to use a step-wise approach of 1) *in silico*, 2) *in vitro*, 3) *ex vivo*, and 4) *in vivo* methods- only in exceptional cases, to be agreed with the Receiving Authority on a case-by-case basis. The use of *in vivo* studies is indeed questionable for ethical reasons therefore these studies are only justified under exceptional circumstances. After negative results of testing the tobacco additive on dependence capacity in the first agreed appropriate method (*in silico*), the next step should be considered and appropriate test(s) should be selected (*in vitro* models), and

so on. It is strongly advised that *in silico* and *in vitro* tests to assess additive-induced addictiveness by independent organisations are developed and validated.

#### **2.4.3.6 Characterising flavour and inhalation facilitation as contribution to attractiveness**

This section will discuss a procedure to assess tobacco products with characterising flavours that are prohibited in the TPD, as well as some other mechanisms that may increase additive-induced attractiveness.

Animal models do not currently exist for the assessment of attractiveness. In humans, the attractiveness of individual tobacco products can be compared in panel studies, surveys and by experimental measures. To test the response to a specific additive, tobacco products can be produced to exclude or include individual additives. However, this type of research is difficult nowadays due to ethical considerations that will often preclude human testing (SCENIHR 2010).

#### **Characterising flavours**

Over 80% of all cigarettes contain at least one flavour, and almost half of all additives in any tobacco product is added as a flavour (Pennings *et al.*, 2016). Flavours may be added to tobacco, cigarette paper, the filter or to the foil wrapper, in an attempt to enhance the tobacco flavour, mask unpleasant odour, and deliver a pleasant cigarette-pack aroma (WHO, 2007). Many different additives are used to create a specific taste/flavour in order to attract certain target groups. Regarding flavour, the new EU Tobacco Product Directive (TPD, Article 7) prohibits cigarettes and roll-your-own tobacco having a characterising flavour other than one of tobacco, as they could facilitate initiation of tobacco consumption or affect consumption patterns (European Union, 2014). A characterising flavour is defined as a '*clearly noticeable smell or taste other than one of tobacco, resulting from an additive or a combination of additives, including, but not limited to, fruit, spice, herb, alcohol, candy, menthol or vanilla, which is noticeable before or during the consumption of the tobacco product.*' The prohibition of tobacco products with characterising flavours does not preclude the use of individual additives outright, but it does oblige manufacturers to reduce the additive or the combination of additives to such an extent that the additives no longer result in a characterising flavour.

Talhout *et al.* published an inventory of methods suitable to assess additive-induced characterising flavours of tobacco products, and concluded that because flavour perception is subjective and requires human assessment sensory analysis in consumer or expert panel studies is necessitated. They recommend developing validated tests for descriptive sensory analysis in combination with chemical-analytical measurements. Testing a broad range of brands, including those with quite subtle characterizing flavours, will provide the concentration above which an additive will impart a characterising flavour (Talhout *et al.*, 2016).

The Commission has recently adopted two implementing acts establishing the rules and mechanism for determining products with characterising flavours<sup>18</sup>.

<sup>18</sup> Commission Implementing Regulation (EU) 2016/779 of 18 May 2016 laying down uniform rules as regards the procedures for determining whether a tobacco product has a characterising flavour

## Tobacco Additives II

The determination of such flavours can concern products before consumption (e.g. before combustion) as well as emissions resulting from normal use (direct and indirect) of the products. To develop a method for determining characterising flavours, and perform some pilot experiments, the Commission contracted the HETOC Consortium in August 2014<sup>19</sup>. The HETOC-consortium carried out, as external contractor, a study on the determination of characterising flavours. Sensory testing complemented by chemical analysis was concluded to be an appropriate method to determine characterising flavours. Their pilot had confirmed that an expert panel is a good approach, but the training phase needs to be more extensive when the real panel is set up. Smelling is the preferred starting point for determining characterising flavours and it was recommended to consider, as a future step, whether a smoking experiment was needed. It was concluded that specific reference spaces for cigarettes and RYO are needed.

Beside the characterising flavour features, other phenomena can contribute to attractiveness. According to the partial guidelines for implementation of Articles 9 and 10 of the WHO framework convention on tobacco control, "attractiveness" refers to factors such as taste, smell and other sensory attributes, ease of use, flexibility of the dosing system, cost, reputation or image, assumed risks and benefits, and other characteristics of a product designed to stimulate use. Note that not all of these properties are related to additives. WHO-FCTC advises Parties to regulate, by prohibiting or restricting, ingredients that may be used to increase attractiveness of tobacco products (WHO, 2012). The FCTC guidelines in relation to the regulation of the contents of tobacco products and regulation of tobacco product disclosures call in particular for the removal of ingredients that increase palatability, create the impression that tobacco products have health benefits, are associated with energy and vitality or have colouring properties.

The TPD includes two references to attractiveness. In the introductory considerations, point 13, it is mentioned that *"In order to carry out their regulatory tasks, Member States and the Commission require comprehensive information on the ingredients and emissions from tobacco products to assess the attractiveness, addictiveness and toxicity of tobacco products and the health risks associated with the consumption of such products."* In article 19, Notification of novel tobacco products, it is mentioned that manufacturers and importers of such a product shall provide *'available scientific studies on toxicity, addictiveness and attractiveness of the novel tobacco product, in particular as regards its ingredients and emissions.'*

In the following, the possibility to assess characteristics other than the characterising flavour as contributors to attractiveness are briefly presented, some of which having the possibility of "Facilitating inhalation or nicotine uptake", which is a criterion of the mandate (category c) included in the ToR).

### **Other sensory attributes which can facilitate inhalation or nicotine uptake**

Low irritation to mouth, throat and chest and satisfaction can facilitate inhalation and possibly nicotine uptake (Jaffe and Glaros, 1986; Kochhar and Warburton, 1990). Mildness, a combination of improved aftertaste, less bitterness, improved mouth feeling and reduced irritation, is reported to be appreciated, especially by younger and beginner smokers, with their undeveloped tastes and a low tolerance for irritation from tobacco smoke (Carpenter *et al.*, 2007).

Additives that influence these sensory attributes, such as mildness, and a pleasant aftertaste, possibly facilitate smoking initiation. By reducing and changing the harshness of the smoke, special target groups may be reached (Carpenter *et al.*, 2005a, Carpenter *et al.*, 2005b, Cummings *et al.*, 2002, Klein *et al.*, 2008, Wayne and Connolly, 2002). A confidential tobacco industry document describes a class of casing materials referred to as ameliorants used to "... smooth out harshness and bitterness and/or eliminate pungent aromas from tobaccos" (Jenkins *et al.*, 1997). Examples of such ameliorants included sugars, cocoa and liquorice. Cocoa, also at levels that do not impart a characterising flavour, can alter cigarette flavour and improve product acceptability (Sokol *et al.*, 2014). Various sugars constitute a large proportion of additives, and the sweetness of the smoke is an important characteristic. Thus, product appeal for starters may be further diminished by regulating trigeminal attributes as well. Smoking panels can be used to assess sensory attributes like irritation, impact, flavour, aftertaste. For irritation, it may also be possible to use *in vitro* models.

Some additives have multiple chemosensory effects. Pyrazines, which are flavours resulting from pyrolysis of amines and sugars, are reported to induce chemosensory effects such as reducing the harshness and irritating effects of nicotine and other tobacco smoke constituents in the airways. In addition, they may reinforce the learned behaviour of smoking, enhance elasticity and help optimise nicotine dosing. Wayne and Henningfield also describe evidence from internal industry documents that "smokers develop a taste for specific flavors or characteristics of tobacco use other than nicotine, and come to associate use with these characteristics" (Wayne and Henningfield, 2008). Vanilla, for example, increases mildness, and smokers will switch to other vanilla-containing brands, but not to brands without vanilla taste. Menthol is also known for its taste, as well as inducing a "cooling" effect which masks the harshness and the taste of raw tobacco (Lawrence *et al.*, 2011).

**Harshness and smoothness.** According to the tobacco industry definition, harshness is a chemically-induced physical effect associated with a roughness, rawness experience generally localized in the mouth and to a lesser degree in the upper reaches of the throat and the trachea due to inhalation of tobacco smoke. Harshness can also cause a drying, rasping, coarse, astringent sensation usually associated with the smoke flavour of Virginia or air-cured type tobaccos. Harshness is classically measured in four degrees: (i) Free – an absence of harshness; (ii) Touching – a slight awareness of a sensation; (iii) Scratchy – some discomfort, a stinging effect; and (iv) Harsh – rough, raw, raspy, coarse, astringent, painful inhalation. Reducing the harshness of the smoke makes it possible to inhale deeper and increase the number of puffs, as physical barriers will be reduced (Wayne and Henningfield, 2008).

The harshness depends partly on the tar/nicotine ratio, but may also be decreased by certain additives such as propylene glycol or levulinates. Tar provides a strong flavour and mouth sensation, masking the harsher, bitter taste of nicotine which may be unpalatable to new smokers and uncomfortable to established smokers. Certain highly

## Tobacco Additives II

---

flavoured additives may also have the same properties to “smoothen” or reduce the harsh irritation of nicotine in tobacco smoke. In order to make the smoke less aversive and permit deeper inhalation, additives such as liquorice and menthol are used. Another approach is to use nicotine salts that do not cause the same irritation, but are still delivering nicotine or keeping the nicotine effect by means of a quicker absorption by ensuring larger amounts of free nicotine (Bates *et al.*, 1999, Keithly *et al.*, 2005). Finally, the addition of humectants such as glycerol, propylene glycol and sorbitol keep the humidity of the tobacco product at a desired level; dry tobacco generates an unpleasant harsh smoke.

**Impact and smoothness.** The term “impact” is widely used in tobacco industry research and documents, and is a tobacco industry term for smokers’ subjective awareness of the drug effects of nicotine. Organic acids have been used since the 1950s to improve “smoothness” of cigarettes. For example, Philip Morris found that lactic acid decreased subjective ratings of harshness and bitterness, and produced a sweeter flavour. Citric additives have been used not only for reduced harshness and flavour modification, but also to modify smoke pH, to neutralize nicotine “impact” (an industry term denoting the organoleptic sensation caused by nicotine; smokers often describe this as “throat catch” or “throat hit”). Tartaric and lactic acids likewise modify the pH of smoke. All of these organic acids increased smoothness and are associated with a decrease in nicotine “impact” (Philip Morris, 1989). However, it is unclear whether these effects are due directly to pH modification. Unregulated botanical and chemical additives might have “multiple-use” purposes, such as enhancing flavour and producing “smoother” cigarette smoke, as well as potentially preventing or masking symptoms associated with smoking-related illnesses (Rabinoff *et al.*, 2007).

**Facilitate the inhalation of tobacco smoke.** Certain ingredients have local anaesthetic effects. As a result, coughing due to inhalation of irritating smoke is dampened and the smoker can inhale the smoke deeper (and more frequently). Examples are etheric oils, such as menthol and thymol.

**Appearance, smell and irritation of tobacco smoke.** In order to make the smoke more attractive not only to the smoker, but also to other people in the proximity of the smoker, it is important that the smoke is appealing and not annoying. This may be attained with additives that make the smoke whiter and more attractive to people seeing the smoke. The TPD prohibits additives having colouring properties for emissions.

Reduced visibility of side-stream is accomplished by the addition of magnesium oxide, magnesium carbonate, sodium acetate, sodium citrate and calcium carbonate to the wrapper (cigarette paper). This has an effect on particle size; particles become smaller and therefore do not easily scatter light and become less visible. Reducing side-stream emissions is based on encapsulating the smoke in an impermeable cone using different types of additives such as potassium succinate, potassium citrate and magnesium carbonate. By combining the use of additives and the look of the tobacco product, greater acceptance of the smoke may be created. Less resistance may be encountered from persons who do not smoke, and at the same time greater pleasure for the smoker may be created. The same agents may also be used to target the individual product at certain target groups (Carpenter *et al.*, 2005a, Connolly, 2004).

The smell of the smoke may be also changed so that it is also more attractive and less irritating (Connolly *et al.*, 2000, Ling and Glantz, 2005). Connolly *et al.* (2000) examined tobacco industry patents covering the function of environmental tobacco smoke masking.

## Tobacco Additives II

---

These strategies include reducing smoke odour, and reducing side-stream smoke visibility and emissions. Methods to neutralize or reduce lingering smoke odour include addition of acetylpyrazine, anethole and limonene to modify the side-stream odour. These compounds have rather low odour thresholds, and are subsequently easily picked up, while they elicit no trigeminal nerve response. Aroma precursors, e.g. polyanethole provided a noticeable fresher, cleaner and less irritating cigarette side-stream aroma, while others (e.g. cinnamic aldehyde, pinanediol acetal) produce slightly sweet, spicy, clean, fresh, and less cigarette-like aroma. In addition, more "classic" additives (e.g. vanillin, benzaldehyde, bergamot oil, cinnamon/cinnamon extract, coffee extract and nutmeg oil) modify sidestream odour.

### **Studying sensory effects**

Neuro-imaging techniques are used to provide insight into brain processes related to sensory perception. The brain integrates sensory inputs such as taste, touch and smell, and the resulting neural activation can be studied by e.g. fMRI and PET (Small, 2012). Many brain areas are involved, such as brainstem, amygdala, and the orbitofrontal cortex. Odours, tastants, and trigeminal stimuli (intranasal irritants) are processed within the olfactory network, gustatory network, and trigeminal network, which are interacting networks (Lundstrom *et al.*, 2011). The widespread network involved in the processing of odorants, tastants, and chemical irritants recruits several key cerebral areas, including those responsible for emotions, memories, and reward. Reward consists of the psychological components learning, affect, and motivation (Berridge and Robinson, 2003). Physiological, emotional, cognitive and sensory responses caused by flavours and odours can be tested, also in relation to 'reward dose' in the brain (SCENIHR, 2010b). In research projects conducted by Philip Morris from 1982 to 1995, electroencephalography (EEG), pattern reversal evoked potential (PREP), and chemo-sensory event-related potential (CSERP) were used to measure physiological, sensory, and cognitive changes related to nicotine and to cigarette additives (Rabinoff *et al.*, 2007).

### **2.4.3.7 Interaction of the additive with other additives/ingredient**

Tobacco smoke is a complex mixture: 9582 chemical components have been identified so far in tobacco and tobacco smoke (Rodgman, Perfetti, 2013), its composition is qualitatively and quantitatively not fully known and may change, depending on the brand. In addition, tobacco being a natural product, its composition is variable over time from batch to batch even within the same brand. One of the major limitations of using *in vitro* and *in vivo* test systems for the toxicological study of inhalational exposures to compounds in tobacco mixtures is the very high number of components in tobacco smoke and the extreme variability of the mixture. The large number of additives (~ 1260 –SCENIHR Tobacco Opinion 1, 2016) present in the Industry's repertoire add further qualitative and quantitative variability to the mixture. The list is open ended, which means that at present there is no restriction on the use of any number of additional additives as alternative chemicals, precursors etc. Moreover, several of these additives are botanical extracts, which, per se are composed of hundreds of components such as flavours, sugars, pH modifiers. These botanical and phytochemical additives are claimed to have a number of properties, including anaesthetic, antibacterial, anticancer, anti-inflammatory, antifungal, and antiviral properties (Rabinoff, 2007), but these 'apparently beneficial' activities cannot justify their use as additives in tobacco products. Indeed, in some cases, they provide for a "smoother" smoking experience by masking

## Tobacco Additives II

---

adverse symptoms caused by smoking (e.g., cough), preventing awareness in the consumer and reductions in cigarette consumption.

The specific purpose and the required concentration is well researched and optimized by tobacco industry before any product is marketed; therefore additives included in the composition of each tobacco product represent a mixture itself. This 'optimal' mixture of additives is intentionally added to a known toxic, carcinogenic and addictive product in order to make the product more palatable by masking the bitter taste, improving the flavour and reduce the irritation of inhaled smoke, optimising nicotine uptake.

The possibility that chemical interactions can occur among different tobacco components and additives and among different additives cannot be excluded. These interaction can consists of direct chemical reactions, forming additional different compounds, or being translated in addition, potentiation or antagonism of the effects induced by additives and tobacco components (being possible that such an interaction occurs at the level of toxicokinetics and at toxicodynamic level). The number of possible interactions and the number of test combinations increase exponentially with increasing numbers of compounds in a mixture. Moreover, the number of experimental groups will also increase with the number of doses of each compound.

As for the general issue of mixture toxicity, in this specific case it can also not be solved by applying an experimental approach, since to test the thousands of possible mixture is not feasible, beside the fact that as previously discussed, their composition is variable. This is an additional reason for not considering suitable the approach of using comparative testing strategies, where differences in effect of the tobacco product with and without the additive are evaluated (see paragraph 3.4.1).

The frameworks for assessing chemical mixtures have been proposed at international and national levels and addressed in several guidance documents.

In most of these documents, the focus is on the mode of action of specific compounds: chemicals with common modes of action will act jointly to produce combination effects that are larger than the effects of each mixture component applied singly. The approach suggested by the non-food SC on mixture toxicity opinion (SCHER, 2012) as well as the one proposed by EFSA (EFSA, 2012 and 2013 on pesticides) can be followed. A case-by-case approach could be useful to define specific testing.

Both the non-food SC and EFSA made use of the WHO/IPCS Framework for Risk Assessment of Combined Exposures to Multiple Chemicals. It is a tiered framework for organising risk assessment tools and data in order to conduct an assessment of combined exposure to multiple chemicals, starting with screening level assessment and proceeding to more complex approaches. The tools and data to be employed are decided on a case-by-case basis by the risk assessor, in order to address the problem at hand, e.g. contaminated site, chemicals in surface water, etc. (Meek *et al.*, 2011).

EU project EuroMix (European Test and Risk Assessment Strategies for Mixtures) will provide a test strategy and test instruments using novel techniques for mixture testing based on new and already existing toxicological tests. The tests will result in data needed for refining future risk assessment of mixtures relevant to national food safety authorities, public health institutes, the European Food Safety Authority (EFSA), the European Chemical Agency (ECHA), industry, regulatory bodies and other stakeholders. <https://www.euromixproject.eu/>

## Tobacco Additives II

---

The following examples show the interactions of compounds with similar function/activity on the one hand and camouflaged effect of botanicals on the other hand revealing the complexity of ascertaining interaction between additives.

Any additives able to interfere with nicotine bioavailability independent on the mechanism can be the cause of addition or synergism of effects. Using at the same time additives altering the pH of tobacco (e.g. alkalising agents such as ammonium compounds facilitating nicotine passage through the cell membrane in the uncharged volatile form), together with substances such as menthol and thymol, facilitating the inhalation of tobacco smoke (due to local anaesthetic effects) or bronchodilators, such as theobromine (generated from cocoa, caffeine and glycyrrhizine) all together would have a non-negligible impact on nicotine bioavailability in the body. Although they present a low concentration singularly, their action can be deemed as non-relevant.

To these considerations should be added the use of additives that interfere with nicotine metabolism, additives such as the gamma-aliphatic lactones group (see SCENIHR opinion 1, 2016) are mild to weak inhibitors of CYP2A5 and CYP2A6. As CYP2A6 is involved in the metabolism of nicotine, the presence of these chemicals could decrease smokers' metabolism of nicotine and maintain higher blood levels (thus increasing smokers' exposure to nicotine by slowing degradation of nicotine in the bloodstream). Furthermore, the inhibitory effect of these chemicals on CYP2A6, although relatively weak in isolation, might be greater when the chemicals act in combination.

Several patents discussed direct "beneficial" physiological actions of botanical additives. In one US patent cited, it was noted that nicotine in cigarettes has a deleterious vasoconstrictive effect on the cardiovascular system, particularly the blood vessels within and surrounding the heart. It was also noted that vaporized niacin in cigarette smoke has a vasodilating action that helps counteract the vasoconstrictive effect of nicotine. Furthermore, additional "beneficial" effects may be obtained when niacin is combined with rutin (a chemical found in many botanicals), "which is considered effective in reducing and preventing capillary fragility." The patent listed 33 botanicals or vegetable materials, or compounds within them, which also appear on the tobacco industry cigarette additive list (Rabinoff, 2007).

Usage of fruit and vegetable extract concentrates/ botanicals can also give an impression of health benefit to the consumer, so could be considered under the TPD Article 7 2 a. This kind of information is very important as more than 100 of 599 documented cigarette additives have pharmacological actions that camouflage the door of environmental tobacco smoke emitted from cigarettes, enhance or maintain nicotine delivery, could increase the addictiveness of cigarettes, and mask symptoms and illnesses associated with smoking behaviours (Rabinoff, 2007).

### **2.4.4 Step 4: Reporting**

In the fourth and last step, a report needs to be drafted on the activities carried out in Steps 1-3, to be sent to the relevant authorities. The report should include an overall evaluation of the results from Step 1-3. In Annex I a reporting template is provided for this purpose.

In order to limit the financial and administrative burden for both industry and authorities, and the subsequent evaluation of the submitted reports by independent institutes, the formation of consortia and joint reports by industry is endorsed.

## 2.5 Specific knowledge gaps for the priority list tobacco additives

In addition to the general strategy described in the previous paragraphs, the major data gaps already identified in Tobacco Opinion 1 for the 15 additive included in the EU Commission priority list have been analysed. The analysis was based on the 'Rational for inclusion' taken from Opinion I.

Based on that, the activities to be performed upfront will be described, in order to identify the most appropriate steps (and end-points) to be carried out and to speed up the process, making possible testing feasible in the 18 month time-frame. In some cases (e.g. identification of CMR properties of the unburnt form) it would be possible to identify whether or not they should enter the evaluation procedure (having properties that do not meet the criteria of the TPD). Starting at the lowest step, for each of the 15 additives on the priority list, recommendations for experimental activities to fill the data gaps recognised in Tobacco Opinion 1 are given. If the outcome is negative (i.e. no effect which does not meet the TPD criteria is demonstrated), they will enter the general strategy of testing and be considered as any other compound. Although the selection was based on the data available, it is recommended to address the extensive literature search also for the 15 priority list chemicals and to apply the WoE approach, as described in step 1.

### 2.5.1 Carob bean

**Synonyms: Locust bean extract, St. Johns bread extract**

**CAS number: 9000-40-2/84961-45-5**

#### Rational for inclusion

Carob bean extract is rich in carbohydrates/sugars. It pyrolyses extensively and the combustion of the high carbohydrate/sugars leads to formation of carcinogenic and toxic compounds (e.g. benzene, polycyclic aromatic hydrocarbons, and phenol), aldehydes (acetaldehyde, formaldehyde, and acrolein), organic acids and caramel colour and flavours.

The aldehydes, acetaldehyde, acrolein and 2-furfural can be generated from the combustion of the sugars contained in carob bean extracts. Different combinations of aldehydes are generated and it is likely aldehydes other than acetaldehyde intervene directly or through the generation of new compounds in the smoke in the inhibition of MAO. Converging data indicate that MAO (monoamine oxidase) inhibitors contained in tobacco and tobacco smoke act synergistically with nicotine to enhance addiction potential (SCENIHR 2010). In addition, toxic aldehydes are also formed. Carob bean extract has a sweet, fruity, chocolaty flavour and contributes to making smoking more attractive by improving flavour, thereby masking its bitter taste and reducing the harshness of smoking.

Carob bean extract is a chemically undefined complex additive containing hundreds of chemicals. Information on the exact chemical composition of this complex tobacco additive is lacking (e.g. carbohydrate, proteins/amino acids and fats, pH modifiers, and psychoactive chemicals). Moreover, analytical information on the number and concentration of flavour compounds including 'character impact compounds', present *per se* and generated upon heating is also not available in the public domain.

## Tobacco Additives II

---

For example, pyrazines are important flavour impact compounds that are formed under pyrolytic conditions via reactions between amines and carbonyl compounds, generally sugars. Several pyrazines are also reported as additives to cigarettes to impart flavour in low tar cigarettes. (Alpert *et al.*, 2015).

This information can facilitate the assessment of the influence on the carob bean extract on palatability, pro-addictive effect and the interaction with other additives and tobacco chemicals.

### Priority activities

**Step 1:** Data on the chemical composition of the carob bean extract should be provided by industry with emphasis on the concentrations of constituents of relevance;

**Step 2:** Some information on the effect of pyrolysis of carob bean extract is available, however, it is necessary to:

- further chemically define its pyrolysis products and
- evaluate the CMR properties of its pyrolysis products.

In case of positive results for genotoxicity/carcinogenicity of its pyrolysis products the use of carob bean extract as a tobacco additive would not meet the TPD requirement and no additional testing would be required.

If it is not proven, the additive can enter the tiered procedure for evaluation. The assessment of its pyrolysis product on palatability, pro-addictive effect and the interaction/synergistic effect with other additives and tobacco chemicals should be presented (Step 4).

### 2.5.2 Cocoa and cocoa products (powder, extracts, shells of cocoa bean etc.)

#### Complex mixture from Theobroma cacao beans

**CAS Numbers: 95009-22-6 (cocoa powder), 84649-99-0, 84649-99-3 (cocoa extract)**

#### Rational for inclusion

Many forms of cocoa additives such as extracts and powders are used frequently and in relatively high amounts. Added as flavour or casing to tobacco (cocoa extract is the most abundantly used, with 847 counts in NL ingredient lists, none in NTM, total number of brands 4265), average (weight %) 0.105 (0.198). The maximum amount of cocoa as tobacco additive is around 1 % of the total tobacco weight (RIVM, 2012).

Regarding toxicity, the effects of cocoa inhalation through smoking have not been studied. The risk associated with the generation of combustion products produced upon cocoa pyrolysis has not been thoroughly studied and thus, conducting an adequate risk assessment for cocoa or its pyrolysis products is currently not possible.

Regarding addictiveness, several pharmacological effects of cocoa-derived ingredients were reported, including the bronchodilatory effect of theobromine and caffeine, which result in improved bioavailability of nicotine, although data available so far indicate that

## Tobacco Additives II

---

the content of theobromine per cigarette seems to be too low to have a bronchodilating effect on the lungs (SCENIHR, 2010). Furthermore, reaction products of tryptophan, phenylethylamine, tryptamine and tyramine, are thought to exert monoamine oxidase-inhibiting properties. In general, the pharmacologically active substances present in cocoa do not exclude a psychopharmacological effect in humans, owing to the low exposure concentrations and/or the inability of these substances to cross or reach the blood-brain barrier. Due to a lack of studies specifically on the psychoactive effects of cocoa added to tobacco, there is insufficient evidence that adding cocoa to tobacco makes cigarettes more addictive.

Regarding attractiveness, the addition of cocoa to tobacco is intended to enhance flavour. More data are needed on the amount of cocoa that imparts a noticeable flavour.

### Priority activities

Based on the available data, cocoa and cocoa products may increase attractiveness and addictiveness and increase inhalation and nicotine uptake. The percentage of cocoa used in cigarettes ranges from 0.2% to 0.66%. The content of theobromine and caffeine per cigarette may be too low to have a bronchodilating effect on the lungs and thereby increase the absorption of nicotine. Therefore, there is uncertainty with regard to the direct effect of cocoa additives on the bioavailability of nicotine and more studies are required.

**Step 2:** Pyrolysis of cocoa results in the generation of minor amounts of phenol, o-, m-, p-cresol, xlenols, catechol, palmitic acid and stearic acid (<0.001% (w/w) in tobacco) and nitrous gases, carbon monoxide and dioxide. Tryptophan combustion can generate 3-amino-1,4-dimethyl-5H-pyrido(4,3-b)indole and 3-amino-1-methyl-5H-pyrido-(4,3-b)indole. Furthermore, tryptophan contains reactive groups and forms reaction products with other compounds during combustion, such as beta-carbolines, including harman (RIVM, 2002). The resulting anti-depressive effects of harman have been suggested to contribute to addiction caused by cigarette smoking. Reaction products of tryptophan, phenylethylamine, tryptamine and tyramine, which are formed during combustion, are thought to exert monoamine oxidase inhibiting properties. Nevertheless, the risk associated with the generation of combustion products produced upon cocoa pyrolysis has not been thoroughly studied and should be carefully evaluated.

**Step 3:** The exposure to cocoa and cocoa-derived ingredients transferred to cigarette smoke in their pure forms is negligible compared with the exposure to these compounds through food and drinks (RIVM, 2002). However, the consequences of the exposure through inhalation have not been studied. Exposure through smoking should not be neglected as it represents two different types of exposure through inhalation of (1) cocoa itself and (2) combustion products of cocoa and its ingredients (RIVM, 2002).

Several mechanisms of enhancing addictiveness of smoking have been proposed, however, it is unclear whether sufficient amounts of psychoactive compounds are produced to exert psychopharmacological effects that would increase addictiveness. Chocolate flavour may make cigarettes more palatable to younger, first time users and may indirectly facilitate dependence by providing enhanced flavour and mouth sensations, potentially serving as a cue for drug reward. Due to a lack of studies specifically directed to the psychoactive effects of cocoa compounds added to tobacco on

## Tobacco Additives II

---

addiction, there is insufficient evidence that the addition of cocoa to tobacco contributes to the addictive properties of cigarette smoking.

The addition of cocoa to tobacco is intended to enhance flavour and therefore smoking may result in a characterising flavour. However, although a considerable percentage of cigarette weight could be cocoa additives, it is not known to what degree this influences the flavour of inhaled mainstream or side stream smoke, and especially how this might influence smoking initiation in youths (Fowles, 2001).

### 2.5.3 Diacetyl

**CAS-nr: 431-03-8**

**Synonyms: butanedione, butane-2,3-dione**

#### Rational for inclusion

Diacetyl exposure may lead to serious lung disease after inhalation. For a proper risk assessment, it is necessary to better characterise the concentrations in mainstream smoke. SCOEL accepted that there is uncertainty about the importance of the genotoxicity of diacetyl. There were no data on carcinogenicity. In addition, it can create a characterising flavour, which can contribute to increasing attractiveness.

#### Priority activities

Based on the rational for inclusion, the main open questions concerning diacetyl are:

- Uncertainty concerning the genotoxicity of diacetyl and no data on carcinogenicity.
- No sufficient data was found concerning the burned (pyrolysis) product.
- Exposure may lead to lung disease after inhalation and should be assessed in appropriate tests.
- Due to the typical flavour of diacetyl it is unclear whether the compound can add to the olfactory cue and attractiveness of the smoking product. The question whether this flavour is distinguishable (attractiveness) and/or has a "smoothing" effect on the smoke (attractiveness/addictiveness) remains unclear.

The first activity to be carried out is related to the need to rule out the genotoxicity of the compound. In case of identification of genotoxic potential, the additive will be out according to the TPD provisions, otherwise it should enter the step-wise procedure.

**Step 1:** Additional data should be searched to address the above mentioned questions

**Step 2:** Pyrolysis products should be studied

**Step 3:** Toxicity testing for inhalation exposure and then for characterizing flavour, inhalation facilitation and addictiveness (considering its potential characterising flavour as well as the "smoothing" effects).

### 2.5.4 Fenugreek extract

**Synonyms: fenugreek (trigonella foenum graecum L.) extract, resin, & absolute**

**CAS number: 84625-40-1**

**Physical properties: Complex mixture, dark brown paste**

## Rationale for inclusion

Natural/botanical concentrates/extracts/resins (e.g. from several fruits - fig, plum, raisins, fenugreek, carob, cocoa, caramel, rum, etc.) form a large number of tobacco additives. They are poorly characterised complexes of several to hundreds of chemicals; the composition further depends upon variable factors influencing botanical source and preparation methods. Although generally recognised as safe as food additives and flavours, this classification is not valid for their inhalation effects and pyrolysis products in tobacco smoke. The combustion/pyrolysis chemistry of each of these additives is not well known in terms of their physiological, toxicological and synergistic additive effects to potentiate the harmful effects of tobacco smoke.

However, many of the botanical extracts have a rich carbohydrate/sugar content, together with varying amounts of proteins, amino acids and other flavour compounds. The pyrolysis of this class of compounds has been well reported. Upon combustion/pyrolysis at temperatures (up to 900°C) attained during smoking, these compounds, especially the carbohydrates, give rise to a complex mixture of toxic, carcinogenic and mutagenic compounds, as well as aroma/flavour compounds.

Compounds formed include smoothing agents (e.g. organic acids), flavours (e.g. caramel), compounds that facilitate nicotine delivery (e.g. aldehydes) and compounds with CMR properties (e.g. PAHs, formaldehyde). Moreover, pyrazines are important flavour impact compounds that are formed under pyrolytic conditions via reactions between amines and carbonyl compounds, generally sugars. Several pyrazines are also added as additives to cigarettes to impart flavour to low tar cigarette (Alpert *et al.*, 2015). The complex mixtures used as additives cause tremendous harm and contribute to CMR properties, addictiveness and attractiveness of tobacco smoke.

## Priority activities

**Step 1:** Data on the chemical composition and specification of the Fenugreek extract (powder, concentrate) should be provided by industry with emphasis on the concentrations of constituents of relevance, production procedure, maximum levels for microorganisms and possible contaminants. According to available information, *Trigonella foenum-graecum* seeds contain mucilage, trigonelline, 4-hydroxyisoleucine, sotolon, diosgenin, phenolic acids, and protodioscin.

The use of fruit and vegetable extract concentrates, such as fenugreek extract, are acknowledged to be beneficial to health, fig extract can thus give an impression of health benefit to the consumer, so could be considered under the *TPD Article 7 2a*. Moreover, as it is also used as medicinal product, this could also give the impression of health protection.

**Step 2:** Fenugreek extract does not transfer intact to the mainstream smoke, but undergoes extensive pyrolysis. Based on the available studies (Baker and bishop 2005), pyrolysis products from fenugreek extract include, pyridine, benzene (carcinogen), toluene and furfural. The pyrolysis products once characterised should be evaluated along the procedure.

If the evaluation shows that it is warranted to move on to step 3, the effects which have been considered as matters of concern (e.g. neuropharmacological activities, CNS depressant and stimulant as well as allergic reaction and exacerbation of asthma) should be investigated first. The burden of proof is on the industry to use the proposed step-

## Tobacco Additives II

wise system and the general strategy described, to prove that the additive is safe on all counts of toxicity, addictiveness and characterizing flavour in the unburnt and burnt form.

### 2.5.5 Fig extract

#### Complex mixture (*figus carica* l. extract)

**CAS number: 90028-74-3 (any other related one if used)**

**CoE number: 198**

#### Rationale for inclusion

Natural/botanical concentrates/extracts/resins (e.g. from several fruits - fig, plum, raisins, fenugreek, carob, cocoa, caramel, rum, etc.) form a large number of tobacco additives. They are poorly characterised complexes of several to hundreds of chemicals; the composition further depends upon variable factors influencing botanical source and preparation methods. Although generally recognised as safe as food additives and flavours, this classification is not valid for their inhalation effects and pyrolysis products in tobacco smoke. The combustion/pyrolysis chemistry of each of these additives is not well known in terms of their physiological, toxicological and synergistic additive effects to potentiate the harmful effects of tobacco smoke.

However, many of the botanical extracts have a rich carbohydrate/sugar content, together with varying amounts of proteins, amino acids and other flavour compounds. The pyrolysis of this class of compounds has been well reported. Upon combustion/pyrolysis at temperatures (up to 900°C) attained during smoking, these compounds, especially the carbohydrates, give rise to a complex mixture of toxic, carcinogenic and mutagenic compounds, as well as aroma/flavour compounds.

Compounds formed include smoothing agents (e.g. organic acids), flavours (e.g. caramel), facilitating nicotine delivery (e.g. aldehydes) and with CMR properties (e.g. PAHs, formaldehyde). Moreover, pyrazines are important flavour impacting compounds that are formed under pyrolytic conditions via reactions between amines and carbonyl compounds, generally sugars. Several pyrazines are also added as additives to cigarettes to impart flavour to low tar cigarettes (Alpert *et al.*, 2015). The complex mixtures used as additives cause tremendous harm and contribute to CMR properties, addictiveness and attractiveness of tobacco smoke.

#### Priority activities

**Step 1:** Data on the chemical composition of the fig extract should be provided by industry with emphasis on the concentrations of constituents of relevance, production procedure, maximum levels for microorganisms and possible contaminants. The use of fruit and vegetable extract concentrates, such as fig extract are acknowledged to be beneficial to health, fig extract can thus give an impression of providing a health benefit to the consumer, so could be considered under the *TPD Article 7 2 a*.

**Step 2:** It does not transfer intact to the mainstream smoke, but undergoes extensive pyrolysis. Information available so far indicates that pyrolysis products include formation of benzene, toluene; in addition the combustion of the sugars lead to the formation of carcinogenic polyaromatic hydrocarbons, a variety of aldehydes, such as acetaldehyde (irritant and possible carcinogen), acrolein (irritant), 2-furfural and a mixture of organic

## Tobacco Additives II

---

acids. Different combinations of aldehydes are generated and it is likely aldehydes other than acetaldehyde intervene directly or through the generation of new compounds in the smoke in the inhibition of MAO. Converging data indicate that MAO (monoamine oxidase) inhibitors contained in tobacco and tobacco smoke act synergistically with nicotine to enhance addiction potential (SCENIHR 2010). The burden of proof is on the industry to use the proposed step-wise system and the general strategy described, to prove that the additive is safe.

### 2.5.6 Geraniol

**CAS number 106-24-1**

#### Rational for inclusion

Geraniol is a known flavouring agent for food and is added to tobacco products for flavouring (one of the factors potentially contributing to attractiveness). More data are needed on the amount of geraniol that imparts a noticeable flavour other than tobacco. No data are available regarding addictiveness.

To perform a toxicity risk evaluation, it is necessary to know the exposure level of geraniol through cigarette smoking. Therefore, research is needed to determine the amount of geraniol in mainstream cigarette smoke. However, considering that the toxicological properties of geraniol are mainly linked to a high potential for skin sensitisation (in addition to skin and eye irritation), no levels considered safe for the majority of consumers could be established from the available data. Geraniol oxidation products (e.g. geranial, epoxy-geraniol, epoxy-geranial) are also potent sensitizers in animals. It could be expected that geraniol would be a respiratory sensitizer (although no information is available on this issue).

It is unknown if geraniol combustion products (about 10-15% of the additive) formed upon smoking a cigarette are toxic or not. Additional pyrolysis experiments are recommended.

#### Priority activities

**Step 1:** The chemical characterization of the additive is of paramount importance: indeed, geraniol can contain the relevant impurity methyleugenol, which is a genotoxic carcinogen. Only in the absence of that impurity, proven by specific certificate of analysis, could geraniol be considered as a possible candidate as a tobacco additive.

**Step 3:** In the case of geraniol, the local toxicity is relevant, as it is a known skin and eye irritant. Furthermore, geraniol and many of its oxidation products (by air oxidation and by metabolic transformation) have already been proven to be skin sensitizers in predictive animal tests. Indeed, geraniol is included among the fragrance substances of clinical importance known to be a prehapten as well as a prohapten.

For skin sensitisation, the SCCS considered that 0.01% could be efficient in limiting elicitation. No data are available for irritation of mucosa in the airways as well as for respiratory sensitisation, but since there is a high potential for inducing that kind of effects, also considering that the few pyrolysis studies available indicate that geraniol is mainly (85-90%) transferred intact to smoke, these should be tested first. In case of

## Tobacco Additives II

---

positive results, the use of geraniol as a tobacco additive should be not allowed and no additional testing would be necessary.

In case it could be demonstrated that geraniol is not a respiratory irritant and sensitizer, the additive can enter the procedure for evaluation.

**Step 1:** The collection of the available data could be useful anyway, although as already indicated in Tobacco Opinion I, this would lead to confirming that data are available to demonstrate that pure geraniol did not induce gene mutations in *Salmonella typhimurium* and mammalian cells and although equivocal response resulted in an *in vitro* clastogenicity test, its genotoxicity can be reasonably considered eligible. In addition, after long-term studies no carcinogenicity potential was attributed to food grade geranyl acetate (29 % citronellyl acetate and 71% geranyl acetate). Therefore those end-points are already addressed. Since the oral absorption has been demonstrated to be >80%, the systemic toxicity after inhalation (also assuming a total absorption through the lung (100%) the effects are not expected to be different. Since the relevant NOAEL are relatively high (558 mg geraniol/kg bw per day for rats and 279 mg geraniol/kg bw/day for mice), systemic general toxicity is not considered relevant at the doses used as tobacco additive. Therefore these end-points are addressed.

**Step 2:** additional standardised pyrolysis experiments are recommended to identify the products formed other than geraniol, to be then evaluated for their toxicological properties plus attractiveness and addictiveness.

**Step 3:** characterising flavour should be addressed first, since geraniol is a known flavouring agent for food and is added to tobacco products for flavouring (one of the factors potentially contributing to attractiveness). More data are needed on the amount of geraniol that imparts a noticeable flavour other than tobacco.

### 2.5.7 Glycerol

**CAS number: 56-81-5**

#### **Rational for inclusion**

Glycerol is added as a humectant to tobacco (to help keep it moist). Its addition is mostly during the "casing" of the tobacco. The amount of glycerol present in cigarettes depends on the cigarette brand. The levels of glycerol added to tobacco in the EU is reported to be on average 1.1 %, with a maximum level comprising 4.5 % of the total weight.

Regarding toxicity, it was reported by the tobacco industry that the transfer rate of glycerol to mainstream smoke is 12 %. A risk assessment procedure using a Margin of Exposure (MOE) analysis concluded that there are risks of effects on the respiratory tract epithelium from glycerol. No thorough assessment on systemic effects was done.

Pyrolysis studies indicate almost 100 % intact transfer of glycerol (Baker & Bishop, 2004; Purkis *et al.*, 2011). However, it was found that less than 0.1 % of the blend glycerol is converted to acrolein in mainstream smoke for different cigarette designs and smoking regimes tested (Yip *et al.*, 2010). Acrolein is a toxic compound that is highly reactive and causes irritation in the respiratory tract. The relationship between added glycerol and acrolein formation is unclear and further research is needed.

## Tobacco Additives II

---

1 Regarding addictiveness, no data were reported to suggest that glycerol plays a role in  
2 smokers' addictiveness to cigarettes.

3 Regarding attractiveness, humectants are added to trap water, thereby keeping  
4 the moisture in the tobacco and preventing it from drying out. Glycerol is, therefore,  
5 considered to positively influence the attractiveness of cigarette smoking, given that  
6 humidification improves the palatability of cigarettes. Glycerol does not have a strong  
7 flavour, and is, therefore, not expected to impart a noticeable flavour.

### 8 **Priority activities**

9 **Step 2 Step 3:** Pyrolysis studies have found that glycerol is converted to acrolein in  
10 mainstream smoke and is also generated during the combustion of many other products  
11 in tobacco. Both glycerol and acrolein cause irritation to the respiratory tract and  
12 acrolein is highly reactive. The relationship between added glycerol and acrolein  
13 formation is unclear and further research is needed.

14 The additive effects of glycerol or its reactivity with other compounds should be further  
15 investigated.

16 No thorough assessment of the systemic effects of glycerol has been done so this should  
17 be looked at further.

### 18 **2.5.8 Guaiacol**

#### 19 **CAS number 90-05-1**

#### 20 **Rational for inclusion**

21 Guaiacol is a known flavouring agent for food and is added to tobacco products for  
22 flavouring (one of the factors potentially contributing to attractiveness). More data are  
23 needed on the amount of guaiacol that imparts a noticeable flavour other than tobacco.

24 Its use as a local anaesthetic can enhance smoke inhalation, thus potentially contributing  
25 to addictiveness.

26 To perform a toxicity risk evaluation, it is necessary to know the exposure level of  
27 guaiacol through cigarette smoking. Therefore, research is needed to determine  
28 the amount of guaiacol in mainstream cigarette smoke.

29 Guaiacol is a severe eye irritant, a skin irritant and also reported to be a respiratory tract  
30 irritant. Other toxicological information on repeated exposure is scant. On the basis of  
31 results on structurally related compounds, effects are likely related to the irritation  
32 potential at the contact site, generating hyperplasia. Apart from the absence of  
33 mutagenicity tested with the Ames test, the only genotoxicity test on mammalian cells  
34 gave positive results (SCE in human lymphocytes). More data are needed for a better  
35 evaluation.

36 Pyrolysis experiments performed with lignin found many guaiacol derivatives besides  
37 guaiacol itself and suggest that it transfers largely intact into the smoke.

### 38 **Priority activities**

## Tobacco Additives II

---

Since the genotoxic potential of guaiacol is of concern, this is the first issue to be clarified. The SCHEER is aware that negative results have been already published by using the *Ames test*; however, positive results were obtained with human lymphocytes: these data have to be confirmed or denied by means of results coming from appropriate *in silico/in vitro* methods (**Step 3**).

In case of positive results, guaiacol would not meet the TPD requirement (see art.7), no additional testing would be necessary, therefore the procedure can go directly to **Step 4**.

If guaiacol could be proved not to have genotoxic properties, the additive can enter the step-wise procedure for evaluation, starting with Step1.

**Step 2:** Pyrolysis products should be then considered. In case there are no objections, the evaluation should proceed to step 3.

**Step 3:** Guaiacol is a severe eye irritant, a skin irritant and also reported to be a respiratory tract irritant: these properties should be specifically addressed as a priority. In addition, properties as local anaesthetic, potentially contributing to addictiveness, should be investigated as a second priority. In case there are no objections, all the other toxicity end-points should be considered.

### 2.5.9 Guar gum

**Synonyms: Guaran, Guar Flour, Jaguar**

**CAS number: 900-30-0 (Guar depolymerised CAS number: 68411-94-9) and others**

#### Rational for inclusion

Guar gum is an extract of the seeds of the guar bean plant. Guar gum consists of high molecular weight polysaccharides and some amount of protein. Reconstituted tobacco is made up of mashed tobacco stems and other parts of the tobacco leaf that would otherwise be discarded. Guar gum (and its derivatives) is added to reconstituted tobacco in cigarettes. Guar gum is also used to prepare the cigarette paper that wraps the tobacco.

The amount of guar gum added to bind the tobacco can make up between 0.6-1.8 % of the total weight of the tobacco used in one cigarette. Guar gum is generally regarded as safe for use in food and cosmetics. However, guar gum does not transfer intact to the mainstream smoke, but undergoes pyrolysis, giving rise to toxic/carcinogenic (e.g. formaldehyde, benzo(a)pyrene and benzene) compounds. Irritating and toxic fumes, gases and acrid smoke can be formed when the additive is heated to decomposition.

Regarding flavours, it is well known that the thermal degradation of sugars and carbohydrates at lower temperatures as in foods contribute to complex aromas. Several flavour compounds were reported due to pyrolysis reactions of guar gum. These flavour compounds singly or in combination with the thousands of other smoke constituents can act synergistically and contribute to the attractiveness of smoking by improving smoke flavour, thereby masking its bitter taste, reducing the harshness of smoking, creating

## Tobacco Additives II

---

1 sensory cues, which all could contribute to the optimisation of nicotine dosing and  
2 enhance abuse potential.

3 Guar gum is hazardous when heated to decomposition, emitting acrid smoke and  
4 irritating fumes. Although some information on the effect of pyrolysis is available from  
5 the internal industry documents, further chemically defining this additive from the point  
6 of view as a tobacco additive and its pyrolysis products would help confirm/facilitate  
7 the assessment of the influence on the carob bean extract on toxicity/carcinogenicity,  
8 palatability, pro-addictive effect and the interaction/synergistic effect with other  
9 additives and tobacco chemicals.

### 10 **Priority activities**

11 **Step 1:** Data on the chemical composition of the guar gum should be provided by  
12 industry with emphasis on the concentrations of constituents of relevance.

13 **Step 2:** Some information on the effect of pyrolysis of guar gum is available, however, it  
14 is necessary to:

15 - further chemically define its pyrolysis products and

16 - evaluate the CMR and other toxicological properties of its pyrolysis products.

17 In case of positive results for genotoxicity/carcinogenicity of its pyrolysis products the  
18 use of guar gum as a tobacco would not meet the TPD requirement; no additional testing  
19 would be required and the procedure could go directly to Step 4.

20 **Step 3:** If CMR properties are not proven by available data, the additive can enter the  
21 step-wise procedure for evaluation, analysing data other than those related to CMR  
22 properties. The assessment of its pyrolysis product on palatability, pro-addictive effect  
23 and the interaction/synergistic effect with other additives and tobacco chemicals should  
24 be analysed.

### 25 **2.5.10 Liquorice**

26 **CAS numbers: 1405-86-3 ( $\alpha$ -D-Glucopyranosiduronic acid), 103000-77-7 ( $\beta$ -D-**  
27 **Glucopyranosiduronic acid)**

### 28 **Rational for inclusion**

29 Liquorice is a natural extract of the root of the liquorice (*Glycyrrhiza glabra*) plant –  
30 logically a not completely defined complex mixture of compounds. When heated to  
31 decomposition, it emits acrid smoke and irritating fumes. More than 400 compounds  
32 were isolated from *Glycyrrhiza* species. Liquorice extracts are used to improve  
33 the organoleptic properties of tobacco smoke, making the harsh cigarette smoke  
34 palatable, thereby enhancing the attractiveness of smoking. The taste and flavour of  
35 tobacco with added liquorice/liquorice root are described as sweet, woody and round.  
36 The major active principle of liquorice is the sweet tasting triterpene glycoside  
37 glycyrrhizin.

38 Glycyrrhizin is a bronchodilator. It is not clear whether the levels present are sufficient  
39 for this effect, although a synergistic effect with other compounds in cigarette smoke  
40 may be expected.

## Tobacco Additives II

---

It is expected to pyrolyse extensively, but there is a lack of information on the pyrolysis products formed, which would help facilitate the assessment of the influence on toxicity/carcinogenicity. Additionally, the effect of liquorice on bronchodilation, alone or in combination with other additives and/or tobacco constituents, needs to be ascertained to better understand its effect on the ease of inhalation of nicotine and other alkaloids, thereby potentiating addictiveness.

### Priority activities

The potential genotoxic effects of liquorice extract have been postulated.

Starting with **Step 1** and if necessary **Step 3** this end-point should be addressed first, to identify alert for the genotoxicity and carcinogenicity of the additive.

**Step 2:** additional standardised pyrolysis experiments are recommended, to identify the products formed during the combustion process of liquorice, to be then evaluated for their CMR properties.

In case results are negative, the evaluation of the effects of long-term inhalation exposure to liquorice with different content of glycyrrhizic acid should consider that both renal and hepatic 11-beta-hydroxysteroid dehydrogenase (converts cortisol to cortisone) as well as hepatic delta-4-5-beta-steroid-reductase (inactivates glucocorticoids and mineralocorticoids) are inhibited by glycyrrhetic acid, which can lead to pseudohyperaldosteronism and elevated blood pressure. The flavonoids licochalcone A and B inhibit the elevation of calcium ions induced by thrombin, in a dose-dependent manner. They also inhibit thrombin-induced platelet aggregation *in vitro*. Licochalcone A and B were tested with human neutrophils and were found to inhibit the formation of leukotrienes B1 and C4, cyto B-induced lysosomal enzyme, platelet activating factor, n-formyl-methionyl-leucyl-phenylalanine and calcium ionophore A.

Hypokalemia, hypernatremia, and water retention are primary problems associated with chronic liquorice ingestion. Changes in the sodium/potassium ratios may result in pH changes. Cardiomyopathy, pulmonary edema, myoglobinuria, ptosis, myopathy, tetany, cramping, seizures, and rhabdomyolysis have also been reported in patients following chronic, excessive liquorice ingestion. Only if it could be demonstrated that chronic liquorice inhalation with tobacco smoke has no systemic effects, could the additive enter the step-wise procedure for evaluation. The safety evaluation of glycyrrhizic acid should be based on the data from humans. Since the oral absorption has been demonstrated to be high, the systemic toxicity after inhalation (also assuming a total absorption through the lung (100%) the effects are not expected to be different. Since the relevant NOAEL is relatively high (2 mg glycyrrhizic acid / kg bw per day for healthy volunteers) and the blood serum half-life is 5 hours, the risk of systemic general toxicity may not be high at the doses used as tobacco additive.

**Step 3:** all the testing regarding general systemic toxicity in chronic inhalation exposure and the one regarding characterising flavour as contribution to addictiveness should be addressed; since liquorice can mask the undesirable characteristics of tobacco smoke and acts as a bronchodilator the possibility for facilitating nicotine uptake should be analysed. More data are needed on the amount of liquorice and glycyrrhizic acid that imparts a noticeable flavour other than tobacco. No data are available regarding addictiveness.

### 2.5.11 Maltol

**CAS Number: 118-71-8**

**Synonyms: 3-Hydroxy-2-methyl-4-pyrone, 3-Hydroxy-2-methyl-4H-pyran-4-one, Palatone, Larixinic acid, Talmon.**

#### Rational for inclusion

Following the EFSA report on maltol (FGE19 and FGE213 and FGE213 rev 1 - EFSA, 2008, 2009 and 2014), the concern for genotoxicity could not be excluded. Therefore, maltol will be on the priority list until data on its genotoxicity are clarified. In addition, possible effects on the CNS must be clarified.

#### Priority activities

The main open questions concerning maltol are therefore uncertainty concerning the genotoxicity.

If the existing information (**Step 1**) does not clarify the uncertainties, some additional testing should be undertaken based on the OECD TG (**Step 3**).

If maltol is proven not to be genotoxic, the additive can enter the step-wise procedure for evaluation.

Since an inhibition of the response of the GABAA receptors in the presence of maltol has been reported which may contribute to CNS stimulation/addictiveness, these are the priority effects that should be investigated in Step 3.

In addition to the above, the following issues were identified:

Maltol and other hydroxyl cyclohexanone derivatives (such as ethyl maltol) are used to augment or enhance the taste of consumable materials, with a typical odour of cotton candy and caramel. No information on minimum levels of odour awareness was found. Reports on the health effect of maltol also underline its potential anti-apoptotic effect. It is unclear whether the anti-apoptotic is specific directed to healthy cells, neoplastic cells and/or cells undergoing mutations.

### 2.5.12 Menthol

**CAS numbers: l-Menthol: 2216-51-5; D-Menthol: 15356-70-4; D/L Menthol: 89-78-1; Menthol: 1490-04-6**

#### Rational for inclusion

Menthol is one of the most commonly used tobacco additives worldwide. It is a monocyclic terpene alcohol that is used primarily for its chemosensory effects of creating perceptions of a cooling minty taste and smell. Menthol is added at a continuum of concentrations, from imperceptible amounts to levels imparting different levels of a characterising flavour.

In addition, several additives and formulations are used to simulate menthol effects. Menthol induces anaesthetic and sensory effects, facilitates deeper inhalation and adds to the impact of nicotine.

---

Tobacco Additives II

---

Menthol is a multifunctional additive. It is an effective anaesthetic, antitussive agent that may increase the sensation of airflow and inhibit respiratory rate, thereby allowing increased lung exposure to nicotine, tar and toxic constituents, while masking reactions like coughing or other early warning signs of respiratory disease. It may increase the absorption and lung permeability of smoke constituents, thereby increasing nicotine and carcinogen uptake. It may also decrease nicotine/cotinine metabolism leading to higher doses of nicotine. It is one of the additives that was originally added to create the impression that a tobacco product has health benefits and/or reduced health risks. It affects multiple sensations including taste, aroma and tactile smoothness, and enhances abuse liability. Its pharmacological actions reduce the harshness of smoke and the irritation from nicotine, and may increase the likelihood of nicotine addiction in adolescents and young adults who experiment with smoking and it may make it more difficult to quit.

In 2011, the FDA Tobacco Products Scientific Advisory Committee (TPSAC, 2011) concluded that menthol 1) impacts youth initiation, 2) contributes to adults continuing to smoke, and 3) has an adverse impact on public health by increasing the numbers of smokers with resulting premature death and avoidable morbidity. Finally, they concluded that the "removal of menthol cigarettes from the marketplace would benefit public health in the United States" (TPSAC, 2011; FDA, 2011).

Independently, the US Food and Drug Administration undertook a thorough review and concluded that the data suggested that menthol use is likely associated with increased smoking initiation by youth and young adults, greater addiction, greater signs of nicotine dependence and less likelihood of successfully quitting smoking. These findings, combined with the evidence indicating that menthol's cooling and anaesthetic properties may reduce the harshness of cigarette smoke and the evidence indicating that menthol cigarettes are marketed as a smoother alternative to non-menthol cigarettes, make it likely that menthol cigarettes pose a public health risk above that seen with cigarettes without menthol (FDA, 2013). The review concluded that although there is little evidence that menthol cigarettes *per se* are more toxic than menthol-free cigarettes, adequate data indicate that menthol presence is associated with increased smoking initiation and greater addiction, especially among young people, as confirmed later by the studies of Nonnemaker *et al.* (2013) and Brennan *et al.* (2015).

Indeed, smokers usually using menthol cigarettes develop greater nicotine dependence, which is likely associated to the anaesthetic properties that reduce the harshness of smoke. In addition, menthol cigarette smokers are less successful quitting smoking (Smith *et al.*, 2014). Recent perception studies confirm earlier work showing that smokers, especially young adults, perceive menthol cigarettes as less harmful (Brennan *et al.*, 2015; Wackowski and Delnevo, 2015).

With regard to toxicity, Noriyasu *et al.* (2013) exposed cell cultures to menthol and nonmenthol smoke and found that cell death was significantly enhanced by mentholated smoke, whereas menthol alone was inert. This suggests a synergistic effect with other smoke-compounds and requires further study. A recent study conducted in mice showed that menthol at low concentration strongly suppressed respiratory irritation due to acrolein and cyclohexane, which are smoke irritants in naïve mice. Additionally, menthol suppressed irritation by tobacco smoke in mice. Menthol increased blood cotinine levels, which is a biomarker of nicotine uptake. Thus, menthol appears to suppress smoke-induced irritation, making it easier to inhale smoke and increasing the dosage of

## Tobacco Additives II

---

nicotine. Due to the similarities in menthol's pharmacology in humans, experiments in animal models suggest that beginning smokers likely prefer menthol-containing cigarettes because their respiratory tract is less irritated. At the same time, these smokers are exposed to higher levels of nicotine and become addicted faster and are less likely to quit smoking (Ha *et al.*, 2015).

At lower application levels, menthol can be used to increase smoothness and reduce harshness in cigarette smoke. This is likely the main reason for use of menthol as an additive, also in "non" menthol brands. Therefore, research to ascertain the physiological and pharmacological impact of low menthol and its interaction with other chemicals, interaction with nicotine, on palatability and inhalation of smoke/nicotine, etc. is recommended.

### Priority activities

**Step 2:** Based on the available studies, pyrolysis of menthol may result in carcinogenic substances (concern category d). There is uncertainty with regard to the nature of the pyrolysis products. Pyrolysis studies should be carried out to identify these products and the products should be evaluated.

**Step 3:** Based on the available data, menthol is concluded to impart a characterising flavour if added in sufficient amounts, facilitate inhalation and addictiveness of tobacco products and increase inhalation and nicotine uptake (concern categories a and c). Uncertainty is low. Further testing to show whether menthol is or is not addictive or does or does not increase attractiveness is not recommended in view of the strength of the data.

Further studies are needed into the suggested synergistic effect of menthol with other smoke compounds. Research to ascertain the physiological and pharmacological impact of low menthol and its interaction with other chemicals, interaction with nicotine, on palatability and inhalation of smoke/nicotine, etc. is recommended.

### 2.5.13 Propylene glycol

**CAS number: 57-55-6**

#### Rational for inclusion

Propylene glycol (PG) is added as humectant to tobacco, rather frequently and in relatively high amounts (1599 counts in NL ingredient lists, 23 in NTM, total number of brand 4265), average (weight %) 1.579 (1.636).

Regarding attractiveness, humectants are added to trap water, thereby keeping the moisture in the tobacco and preventing it from drying out. Internal tobacco industry documents reported that adding 3-7 weight percent of PG increased the mildness and reduced irritation (although this is higher than amounts typically present in tobacco cigarettes). Propylene glycol is, therefore, considered to positively influence the attractiveness of cigarette smoking given that humidification improves palatability of expected to impart a noticeable flavour.

Regarding addictiveness, no data were reported to suggest that propylene glycol plays a role in smokers' addictiveness to cigarettes.

## Tobacco Additives II

---

Regarding toxicity, it was reported by tobacco industry that the transfer rate of propylene glycol to mainstream smoke is 10 %. A risk assessment procedure using a Margin of Exposure (MOE) analysis concluded that risks of effects on the respiratory tract epithelium from propylene glycol exist. No thorough assessment on systemic effects was made.

Propylene oxide is regarded as possibly carcinogenic to humans and trace amounts are present in propylene glycol. Additionally, pyrolysis of propylene glycol results in formation of small amounts (<10 %) of 1,3-propylene glycol, acetol or acetic anhydride, and pyruvaldehyde.

Finally and importantly, propylene glycol and/or its combustion products is only one component out of the thousands of compounds contained in cigarette smoke, thus additive effects or reactions with other compounds are likely to occur.

### Priority activities

**Step 1:** Since propylene oxide, which is regarded as possibly carcinogenic to humans (IARC Group 2B carcinogen), is found in trace amounts in industrially-produced propylene glycol, the specification should be provided.

Data available should be collected to prove or disprove whether propylene glycol increases the risks of effects on the respiratory tract epithelium (being added to tobacco as a humectant in relatively large quantities, possibly increasing the attractiveness of cigarette smoking)

**Step 2:** Pyrolysis products should be better characterised also considering that Propylene oxide has been reported to be generated during cigarette smoking.

**Step 3:** The effect of propylene glycol on inhalation facilitation to cigarettes at levels found in European cigarettes (range of 0.2 to 2.4%) warrants investigation. The additive effects of propylene glycol and/or its reactivity with other compounds should be further investigated.

No thorough assessment of the systemic effects of glycerol has been done so this should be looked at further.

### 2.5.14 Sorbitol

**CAS number: 50-70-4**

#### Rational for inclusion

Sorbitol is added as a humectant to tobacco (210 times in NL ingredient lists, 30 in NTM, total no of brands 4265), average (weight %) 0.232 (0.458).

Regarding attractiveness, humectants are added to trap water, thereby keeping the moisture in the tobacco and preventing it from drying out. Sorbitol is, therefore, considered to positively influence attractiveness of cigarette smoking given that humidification improves palatability of cigarettes. Sorbitol gives tobacco smoke a slightly bitter taste and a vague odour of cellulose and is, therefore, not expected to impart a noticeable attractive flavour when used in higher amounts.

## Tobacco Additives II

---

Regarding addictiveness, no data were reported to suggest that sorbitol plays a role in smokers' addictiveness to cigarettes. However, its combustion products, such as acetaldehyde and formaldehyde, were proposed to increase the addictive effect of nicotine, although data on acetaldehyde produced by pyrolysis entering the brain through the smoke inhaled are inconclusive (SCENIHR 2010).

Regarding toxicity, sorbitol was reported to pyrolyse at 900°C to compounds, such as 2-furfural (31.4 %, see section on furfural), acetaldehyde (irritant and possible human carcinogen), formaldehyde (irritant, carcinogen). Other pyrolysis products of sorbitol include furan, 2-methyltetrahydrofuran, propionaldehyde, acetone, methanol, and carbon monoxide (Baker and Bishop, 2004). Further research is needed to confirm these effects, especially if sorbitol pyrolysis results in carcinogenic compounds.

Finally, it must be borne in mind that sorbitol (and/or its combustion products) is only one component out of the thousands of compounds contained in cigarette smoke, thus additive effects or reactions with other compounds are likely to occur.

### Priority activities

**Step 2:** The main concern for sorbitol to be addressed, before it can enter the evaluation procedure, is the formation of toxic pyrolysis and CMR products. Pyrolysis experiments must be carried out using conditions relevant for cigarette smoking (see section 3.4.1). In case of positive results, sorbitol as a tobacco additive would not meet the TPD requirements and no additional testing would be necessary, going directly to Step 4.

In case it could be demonstrated that no toxic or carcinogenic pyrolysis products are formed, the additive can enter the step-wise procedure for evaluation.

In particular, it needs to be assessed, in **Step 3**, whether it increases inhalation facilitation of cigarette smoking. It is not expected that sorbitol will give a characterising flavour that is attractive. No data are available regarding addictiveness.

### 2.5.15 Titanium Dioxide

**CAS numbers: 13463-67-7 (mixture of mainly rutile and anatase); 1317-80-2 (rutile); 1317-70-0 (anatase)**

#### Rational for inclusion

The SCCS evaluated its use as cosmetic ingredient (sunscreen). With regard to inhalation toxicity, it was concluded that in subacute repeated dose inhalation toxicity studies, nano-size TiO<sub>2</sub> induce an acute inflammation in the lungs, that may be reversible depending on the dose and the time after exposure. In view of this, acute inflammation (spray) applications, which may result in inhalation exposure, were not recommended by the SCCS. Both nano and non-nanosize titanium dioxide were classified by IARC as a Group 2B carcinogen (i.e. possibly carcinogenic to humans) (IARC, 2010).

To perform a risk evaluation, it is necessary to know the exposure level of titanium dioxide through cigarette smoking. Therefore, research is needed to determine the amount of titanium dioxide in mainstream cigarette smoke. Because inhalation toxicity is also related to the size of the particles, a distinction needs to be made between nano and non-nano size.

1   **Priority activities**

2   **Step 2:** Not applicable because titanium is already in its highest oxidised state.

3   **Step3:** In subacute repeated dose inhalation toxicity studies, nano-size TiO<sub>2</sub> induces  
4   an acute inflammation in the lungs. Based on the available data, titanium dioxide is  
5   classified as a IARC Group 2B carcinogen (concern category d).

6   Within the scope of the EU CLP Regulation, a proposal for harmonised classification of  
7   TiO<sub>2</sub> was submitted (ECHA,CLH report, Proposal for Harmonised Classification and  
8   Labelling Based on Regulation (EC) No 1272/2008 (CLP Regulation), Annex VI, Part 2,  
9   Substance Name: Titanium dioxide, Version 2, May 2016). It is proposed to classify TiO<sub>2</sub>  
10   specifically by inhalation as Carcinogen Cat 1B. It was concluded that no carcinogenic  
11   concern was reported by both oral and dermal routes but that there is sufficient evidence  
12   of carcinogenicity in experimental animals after inhalation. Indeed, a causal relationship  
13   has been established between TiO<sub>2</sub> and the increase of malignant lung tumours in female  
14   rats and benign lung tumours in males and female rats in 2 inhalation and 2 instillation  
15   studies. Human data do not suggest an association between occupational exposure to  
16   TiO<sub>2</sub> and risk for cancer. However, all these studies have methodological limitations and  
17   the level of exposure reported is debatable. Although the full mode of action is still  
18   unclear, an inflammatory process and indirect genotoxic effect through ROS production  
19   seems to be the major mechanism to explain the effects induced by TiO<sub>2</sub>. It is  
20   considered that this mode of action is principally due to the biopersistence and poor  
21   solubility of the TiO<sub>2</sub> particles Evidence may be provided to address the uncertainties  
22   with regard to the genotoxicity and carcinogenicity of TiO<sub>2</sub> by inhalation for humans.

### 3 OPINION

In line with Article 6 of the Tobacco Products Directive 2014/40/EU, the Commission has established a priority list of 15 additives contained in cigarettes and roll-your-own tobacco subject to enhanced reporting obligations that is to be updated on a regular basis. In Opinion 1, SCENIHR advised the Commission by providing a list of additives to consider for inclusion on this priority list.

The TPD prescribes that Member States shall require manufacturers and importers of tobacco products to carry out comprehensive studies on these additives. The SCHEER was asked to provide guidance on the type and criteria for these comprehensive studies, and the most suitable methodologies to be used. This advice will guide comprehensive studies on the first list of 15 priority additives, as well as for additives on future updated lists.

In the first part of the current Opinion, SCHEER proposed a step-wise strategy (Section 3.4), as the most pragmatic and efficient way to proceed in the assessment of the toxic and addictive effects as well as characterising flavour properties, and inhalation facilitation, as contributing to attractiveness of tobacco additives. The tiered approach proposed by DKFZ (DKFZ, 2010) was used as a starting point and adapted to include the evaluation of attractive and addictive effects of additives. The proposed strategy ensures that testing is minimised.

First, the chemical specification of the additive has to be available (Step 1). Then an evaluation of the available literature needs to be carried out, for the additive in its unburnt form (Step 1) and its pyrolysis products (Step 2). If no data are available on the identity of the pyrolysis products, they need to be generated using relevant test conditions (Step 2). Here, it needs to be noted that no validated methods are available for the pyrolysis of tobacco additives.

In case data retrieved in Step 1 and 2 are not sufficient or robust enough to make the evaluation possible, non-testing methods such as QSAR and read across are proposed, followed by *in vitro* approaches. Regarding types of effects, unless the previous step highlighted some concern for a specific end-point, CMR properties and toxicity are assessed first, as accepted methods and evaluation frameworks are available, followed by characterising flavour, because procedures are available for the assessment of these end-points. Next, addictiveness is assessed, an effect for which no validated tests are available, although mechanisms underlying addictiveness are known. It is strongly advised that *in silico* and *in vitro* test to assess additive-induced addictiveness by independent organisations are developed and validated.

The issue related to interaction of the additive with other additives/ingredients is also considered. The industry is obliged to provide all known information on the interaction of additives and their pyrolysis products leading to the intended formation of flavours / pH modifiers/ smoothing agents and other important compounds.

In addition to proposing specific steps and tests to be considered by industry, some general criteria were also identified. A pre-ambule here is that additives in tobacco products have no health or other benefits for the consumer, but rather promote use of and addiction to an extremely toxic product. Therefore, a risk-benefit analysis is not the appropriate paradigm for assessing the additive. By consequence, we advise that the level of proof of safety must be set very high, and the precautionary principle as a quintessential element of preventive toxicology should come into full force. The same

---

Tobacco Additives II

---

reasoning applies to the addictive effects and characterising flavour of tobacco additives, as they will indirectly lead to health consequences by increasing consumption of the product.

In order to provide a relevant outcome to the question whether an additive contributes to the toxicity, characterising flavour or addictiveness of the tobacco product, the study design must adhere to some methodological criteria. Most importantly, the test outcomes should be relevant for tobacco smoking. This implies that they should be related to actual human exposure and tobacco-induced diseases, and be relevant not only for acute or subchronic, but also for chronic exposure in intermittent use sessions (Johnson *et al.*, 2009).

Furthermore, comparative toxicity testing strategies, where differences in effect of the tobacco product with and without the additive are evaluated, are not considered suitable. Due to the high intrinsic toxicity of tobacco products, it is challenging to demonstrate any differences, whether they are increases or decreases, induced by an additive with the currently available tests and methodologies (Kienhuis *et al.*, 2016). Very sensitive tests would be required, with a clear dose-response relationship, in order to show any differences from these high background effects. As such tests are not currently available, no comparative studies (tobacco product with and without additives) will be considered for the moment, since these studies lack discriminative power. Comparative studies are also not endorsed to study the effect of additives on addictiveness and inhalation facilitation, for the same reasons.

Another problem with comparative testing is that the outcomes would only apply to that specific tobacco test product. The results (related to toxicity, addictiveness and attractiveness) cannot be generalised to all products and brands, having a different composition with respect to tobacco type, blend and additives. Therefore the obtained results may not lead to general prohibition/acceptance of specific additives but rather to prohibition/ acceptance on a product-by-product basis (DKFZ, 2010). Instead of using a comparative study design, the effects of the pure additive, and its pyrolysis products, must be considered in a relevant testing strategy, such as the tiered approach proposed by DKFZ (DKFZ, 2010), which has been adapted by SCHEER (Section 3.4).

For ethical reasons, animal studies are not endorsed to assess the safety of a tobacco additive. Similar to cosmetics, it is not necessary to use tobacco products. Moreover, apart from being unnecessary, tobacco products are highly harmful with no benefits to individual or public health. As additives are used for product improvement, often contributing to detrimental effects for the consumers (i.e. attractiveness or addictiveness), there is no health benefit in using tobacco additives. For the hazard assessment of tobacco additives, relevant and valid *in silico* and *in vitro* methods exist. QSAR methodology has been used for decades successfully for predicting toxicological and pharmacological properties of chemicals. The same applies to *in vitro* methods, which were validated and accepted for the adverse outcome they are supposed to measure. Additionally, many promising *in vitro* methods are currently being developed to assess different adverse outcomes from apoptosis and gene expression to inflammation and respiratory diseases.

Therefore, as a principle, only *in silico*, and *in vitro* studies will be considered, following the EU policy to ban animal studies for chemicals to be used in voluntary products such as cosmetics (EU Regulation no. 1223/2009). Human studies are discouraged. These

## Tobacco Additives II

---

1 may only be used in case of flavour assessment, but only if the study subjects are not  
2 exposed to the harmful smoke emissions of tobacco products.

3 The major data gaps already identified in Tobacco Opinion 1 for the 15 additive included  
4 in the EU Commission priority list have been analysed (Section 3.5). Based on the data  
5 gaps described in the 'Rationale for inclusion' taken from Opinion I, the activities to be  
6 performed upfront have been described, indicating the most appropriate steps (and end-  
7 points) to be carried out and then used for the evaluation, in order to speed up  
8 the process making possible testing feasible in the 18-month timeframe.

9 In general, important data gaps for the 15 priority additives are information on  
10 addictiveness and characterising flavour or inhalation facilitation, contributing to  
11 attractiveness, as well as on the identity of the pyrolysis products. In the past, major  
12 emphasis was put on toxicity, whereas limited research was carried out on addictiveness  
13 and even less on attractiveness. Regarding toxicity, data were often taken from the food  
14 sector, where pyrolysis and inhalation are not an issue.

15 In conclusion, this Opinion provides general guidance to tobacco industry to conduct  
16 studies and prepare reports on the 'safety' of Tobacco additives to be sent to  
17 the relevant authorities. To this purpose, a reporting template is provided as well. In  
18 addition, specific advice is given for priority testing activities to fill the data gaps  
19 recognised in Tobacco Additives Opinion 1. In order to limit the testing and  
20 administrative burden, the formation of consortia and joint reports by industry is  
21 endorsed. It needs to be noted that there is a lack of (validated) methods for  
22 the pyrolysis of tobacco additives. Similarly, no addictiveness and attractiveness tests  
23 (apart from a procedure for characterising flavours) are available, a knowledge gap  
24 already noted by the SCHENIHR in 2010 in its report 'Addictiveness and attractiveness of  
25 tobacco additives', and the situation has not improved since then. It is advised that  
26 independent bodies or organisations begin conducting relevant research.

## **7 Annex I**

### **GUIDANCE AND TEMPLATE**

#### **A. GENERAL ISSUES**

This brief guidance intends to support the understanding of “what was done”. Authors should take responsibility to be clear of the definitions and provide proper citations for any terms/data they use.

##### **1. TITLE PAGE**

The title page should contain the following information:

Identification of the additive

Abstract and keywords, if applicable

Name of sponsor (and bodies that fund or commission the analysis)

Name and affiliation of person or persons responsible for producing and signing off the report

Date and version of report.

##### **2. SUMMARY**

The summary is intended to provide a concise description of the key elements.

##### **3. REPORTING SOURCES OF INFORMATION**

This section should describe any data source or sources that were used (e.g. existing data and/or databases, *in silico* techniques/models used, experimental studies).

This section addresses the key features of the design.

The rationale for the overall study design should be documented

If needed also ethical approval (approval number – approved by ...- date) for *in vivo* experiments (animals or humans) should be given.

##### **4. REPORTING DATA QUALITY / DATA COLLECTION QUALITY ASSURANCE**

This section addresses the reporting of the elements of data collection and pre-processing that could influence data quality.

- How was the literature search been conducted and which used quality controls were in place

- Were in own experimental studies quality controls in place:

*In silico*

*In vitro*

*In vivo*

##### **5. PUBLIC SUMMARY OF THE DOSSIER**

The target group of a public summary is a non-professional public. The structure and content of the public summary shall be elaborated accordingly. The document should be less extensive comparing to the *summary*. A scientific/professional terminology shall be avoided if possible.

**6. CD/DVD**

The applicant shall submit a dossier with the full information on standard electronic media such as CD ROMs or DVDs. Two or three CD ROMs or DVDs shall be submitted.

Common electronic formats should be used (e.g. MS Office, Adobe Acrobat Reader) allowing content copying and printing (no content copy protection). The text of the files should be searchable using the search facilities of standard software packages. The CD or DVD shall be structured in folders that reflect the structure of the submission.

Also a full paper copy of the dossier is requested, it has to be declared by the applicant on a separate sheet or in the accompanying letter that the electronic and the paper versions are identical.

**7. LIST OF PARTS OF THE DOSSIER REQUESTED TO BE TREATED AS CONFIDENTIAL**

Applicants have the right to request a confidential treatment of certain information. They shall indicate which sections and data they wish to be treated as confidential (and give verifiable justification for each part for which a confidential treatment is required).

Furthermore, the applicant shall provide the Commission with two electronic versions of the dossier, namely the complete dossier and a second version of the complete dossier without confidential information.

**B. SPECIFIC ISSUES – GENERAL LAYOUT****1. CHEMICAL AND PHYSICAL SPECIFICATIONS OF ADDITIVE****A. Chemical identity**

Primary name and/or INCI name

Chemical names

Trade names and abbreviations

CAS / EC number

Structural formula

Empirical formula

**B. Physical form****Molecular weight****Purity, composition and substance codes****Impurities / accompanying contaminants****Solubility****Partition coefficient (Log Pow)****Additional physical and chemical specifications**

Where relevant:

- organoleptic properties (colour, odour, taste if relevant)

- vapour pressure

- pKa

- ...

### C. Function and use of the additive

## 2. (Each identified) PYROLYSIS PRODUCTS

### Chemical identity

### Molecular weight

### % formed (at specific temperature)

### Solubility

### Partition coefficient (Log Pow)

### Additional physical and chemical specifications

Where relevant:

- organoleptic properties (colour, odour, taste if relevant)

- vapour pressure

- density

-- pKa

- ...

## 3. TOXICOLOGICAL EVALUATION

For each study, independent whether is an own study or data were assessed from literature, a full study report should be given:

- If data is derived from an original (own) study, all original (rough) data should be submitted
- If data is derived from literature, the full paper/report should be submitted.

Next to the full report a study summary should be submitted, including, if applicable, the following (the summary reports should usually only exceed 1 page):

*Guideline:*

*GLP/quality control measure:*

*Test system: (in silico/in vitro/in vivo/human):*

*N° independent assessments – group size:*

*Test substance:*

*Batch:*

*Purity:*

*Vehicle:*

*Dose level:*

*Route of exposure:*

*Exposure duration:*

*Exposure duration & observation period:*

*Study date/period:*

*Specific methodological issues:*

*Brief summary of the results: (summary):*

*Brief conclusion:*

If more studies were reported for one toxicological endpoint, a final conclusion should be formulated, taking into account the data of the different related studies.

**Summary:** Finally, at the end of the section Toxicology a brief general conclusion should be formulated.

#### 4. ADDICTIVENESS ASSESSMENT

For each study, independent whether is an own study or data were assessed from literature, a full study report should be given:

- If data is derived from an original (own) study, all original (rough) data should be submitted
- If data is derived from literature, the full paper/report should be submitted.

Next to the full report a study summary should be submitted, including, if applicable, the following (the summary reports should usually only exceed 1 page):

*Guideline:*

*GLP/quality control measure:*

*Test system: (in silico/in vitro/in vivo/human):*

*N° independent assessments – group size:*

*Test substance:*

*Batch:*

*Purity:*

*Vehicle:*

*Dose level:*

*Route of exposure:*

*Exposure duration:*

*Exposure duration & observation period:*

*Study date/period:*

*Specific methodological issues:*

*Brief summary of the results: (summary):*

*Brief conclusion:*

If more studies were reported for one addictiveness endpoint, a final conclusion should be formulated, taking into account the data of the different related studies.

**Summary:** Finally, at the end of the section addictiveness assessments a brief general conclusion should be formulated.

#### 5. ATTRACTIVENESS ASSESSMENT

For each study, independent whether is an own study or data were assessed from literature. A full study report should be given:

- If data is derived from an original study, all original (rough) data should be submitted
- If data is derived from literature, the full paper/report should be submitted.

Next to the full report a study summary should be submitted, including the following (the summary reports should usually only cover 1 page):

*Guideline:*

*GLP/quality control measure:*

*Test system: (in silico/in vitro/in vivo/human):*

*N° independent assessments – group size:*

*Test substance:*

*Batch:*

*Purity:*

*Vehicle:*

## Tobacco Additives II

---

- 1 *Dose level:*
- 2 *Route of exposure:*
- 3 *Exposure duration:*
- 4 *Exposure duration & observation period:*
- 5 *Study date/period:*
- 6 *Specific methodological issues:*
- 7 *Brief summary of the results: (summary):*
- 8 *Brief conclusion:*

9 If more studies were reported for one attractiveness endpoint, a final conclusion should be  
10 formulated, taking into account the data of the different related studies.

11 **Summary:** Finally, at the end of the section attractiveness assessments a brief general conclusion  
12 should be formulated.

### 13 **6. ASSESSMENT OF INTERACTION OF ADDITIVES WITH OTHER ADDITIVES/INGREDIENTS**

14 For each study, independent whether is an own study or data were assessed from literature. A full  
15 study report should be given:

- 16 - If data is derived from an original study, all original (rough) data should be submitted
- 17 - If data is derived from literature, the full paper/report should be submitted.

18 Next to the full report a study summary should be submitted, including the following (the summary  
19 reports should usually only cover 1 page):

- 20 *Guideline:*
- 21 *GLP/quality control measure:*
- 22 *Test system: (in silico/in vitro/in vivo/human):*
- 23 *N° independent assessments – group size:*
- 24 *Test substance:*
- 25 *Batch:*
- 26 *Purity:*
- 27 *Vehicle:*
- 28 *Dose level:*
- 29 *Route of exposure:*
- 30 *Exposure duration:*
- 31 *Exposure duration & observation period:*
- 32 *Study date/period:*

**Short title:** Snus use and prostate cancer survival

**Keywords:** cancer survival, prostate cancer, smoking, snus, tobacco use

**Article category:** Research Article

**Novelty and Impact:** Snus – a smokeless tobacco product often touted as a safe alternative to cigarettes – was independently associated with risks of overall and prostate cancer-specific mortality that were comparable to cigarette smoking. Our findings along with other epidemiological and laboratory work suggest that nicotine and/or other components of smokeless tobacco may play independent roles in the progression of prostate cancer. These results have critical implications for the public health impact of smokeless tobacco products such as snus.

## Abstract

Smoking is associated with prostate cancer mortality. The Scandinavian smokeless tobacco product snus is a source of nicotine but not the combustion products of smoke, and has not been studied with respect to prostate cancer survival. The study is nested among 9,582 men with incident prostate cancer within a prospective cohort of 336,381 Swedish construction workers. Information on tobacco use was collected at study entry between 1971 and 1992, and categorized into (1) never users of any tobacco, (2) exclusive snus: ever users of snus only, (3) exclusive smokers: ever smokers (cigarette, cigar, and/or pipe) only, and (4) ever users of both snus and smoking. Hazard ratios for prostate cancer-specific and total mortality for smoking and snus use based on Cox proportional hazards models adjusted for age, calendar period at diagnosis, and body mass index at baseline. During 36 years of follow-up, 4,758 patients died – 2,489 due to prostate cancer. Compared to never users of tobacco, exclusive smokers were at increased risk of prostate cancer mortality (HR 1.15, 95% CI: 1.05-1.27) and total mortality (HR 1.17, 95% CI: 1.09-1.26). Exclusive snus users also had increased risks for prostate cancer mortality (HR 1.24, 95% CI: 1.03-1.49) and total mortality (HR 1.19, 95% CI: 1.04-1.37). Among men diagnosed with non-metastatic disease, the HR for prostate cancer death among exclusive snus users was 3.17 (95% CI: 1.66-6.06). The study is limited by a single assessment of tobacco use prior to diagnosis. Snus use was associated with increased risks of prostate cancer and total mortality among prostate cancer patients. This suggests that tobacco-related components such as nicotine or tobacco-specific carcinogens may promote cancer progression independent of tobacco's combustion products.

## Introduction

The medical community and the general public generally accept that cigarette smoking is a major determinant of mortality. Perhaps less appreciated, a pooled analysis of nearly one million people found that 17% of this excess mortality was due to causes of death not typically associated with smoking, including prostate cancer.<sup>1</sup> The 2014 Surgeon General's report found current or recent smoking was associated with an increased risk of advanced-stage prostate cancer and death from prostate cancer, although not associated with overall incidence of the disease.<sup>2-7</sup> Because the specific compounds in cigarettes that most strongly influence prostate cancer outcomes have not been identified, it is not clear the extent to which other tobacco products, some of which are increasing in popularity, also pose risks.

Snus, a moist smokeless tobacco product common in Scandinavia, is of interest in the study of the biological effects of tobacco, as users are exposed to high levels of nicotine and other compounds over long periods of time, but without exposure to tobacco combustion products known to influence cancer risk and outcomes.<sup>8,9</sup> The potential effect of snus on cancer progression is also of policy interest, as snus is generally suggested as a risk-reducing alternative to smoking by authorities including the World Health Organization.<sup>10-13</sup> In fact, tobacco companies have introduced and promoted the use of snus outside of Sweden as a healthier alternative to smoking over the past decade, and have sold it in the United States since 2006.

No study to date has investigated whether snus use is, in fact, a less detrimental alternative to smoking among men with prostate cancer. We used data from a cohort of male Swedish construction workers to study the associations of both smoking and snus use with prostate cancer mortality among 9,582 men diagnosed with prostate cancer between 1971 and 2007.

## Patients and Methods

*Study population and follow-up.* The Swedish construction industry's Organization for Working Environment, Safety and Health (Bygghälsan) offered annual preventive health check-ups to all construction workers in the industry between 1969 and 1992. A total of 343,811 male workers had at least one visit between 1971 and 1992. Each visit included detailed questions about tobacco use.

The nationwide Swedish Cancer Register, established in 1958 and 96-98% complete,<sup>14</sup> was used to identify incident cases of prostate cancer to form the study population for this analysis. Men with previous history of any cancer at study entry were excluded. We included 9,582 workers with a diagnosis of prostate cancer after the time of the first study visit and between 1971 and 2007. Mortality and cause of death through 2007, the most recent date for which mortality data was available, were ascertained through linkage to the nationwide Swedish Death Register, which has been shown to have high reliability for cause-of-death among prostate cancer patients.<sup>15-17</sup> Follow-up for mortality in Sweden is essentially complete.

Information on tumor characteristics for men with newly diagnosed prostate cancer was available from the National Prostate Cancer Register (NPCR) of Sweden, which has been nation-wide since 1998 with a capture rate of 98% compared to the Swedish Cancer Register. Thus tumor characteristics were available for 5,346 men (56% of total). In this subset of cases, we defined risk categories using a modified version of the National Comprehensive Cancer Network Practice Guidelines in Oncology, Version.1.2010, based on stage, Gleason score, and serum prostate specific antigen (PSA) at diagnosis.<sup>18</sup> Low risk was defined as clinical stage T1 or T2, Gleason score 2-6, and PSA <10 ng/ml. Intermediate risk was stage T1-T2, Gleason score 7, and/or PSA 10 to <20 ng/ml. High risk localized disease was stage T3-T4 and/or Gleason 8-10, and/or PSA 20-<50 ng/ml. Regionally metastatic disease was defined as N1 and/or PSA 50 to <100 ng/ml and M0/MX. Distant metastases was defined as M1 and/or PSA ≥100 ng/ml.

*Assessment of tobacco use.* Between 1971 and 1975, participating workers filled out a 200-item questionnaire with detailed questions about smoking, and snus use. Collection of information on tobacco use was not done in 1976-1977 but resumed in 1978 with a questionnaire completed by the examining nurse. All data were compiled in a central computerized register. The number of total visits per person ranged from 1 to 13. However, we limited our analysis to exposure information collected in the first visit because the number and timing of visits may be linked with mortality. Based on the first visit, never, past and current tobacco use was obtained and past and current users were combined. Therefore, men were classified as (1) never users of any tobacco, (2) ever users of snus only ("exclusive snus"), (3) ever smokers only: cigarette, cigar, and/or pipe ("exclusive smoking"), and (4) ever users of both snus and smoking (either concurrently or sequentially).

*Statistical analysis.* Each worker contributed person-time from the date of prostate cancer diagnosis to the date of death, emigration, or end of study, December 31, 2007, whichever came first. The association between tobacco use and either prostate cancer-specific or total mortality was studied using Cox proportional hazards models with time since cancer diagnosis as the underlying time scale. Models were stratified by age at diagnosis (<60 years, 60-64, 65-69, 70-74, 75+ years) and time period of diagnosis (1971-1984, 1985-1994, 1995-2007), and were adjusted for body mass index (BMI) at baseline (continuous) and time between baseline exam and cancer diagnosis (continuous). In the subset of patients with clinical data, additional models were adjusted for stage, grade, and PSA at diagnosis. We also studied the association between tobacco use and death among men diagnosed with non-metastatic disease, i.e., excluding those with evidence of regionally spread disease and distant metastases, under the hypothesis that lifestyle factors may play a greater role in survival among men with less advanced disease at diagnosis.

SAS statistical software (release 9.2) was used for the analysis. The study was approved by the Stockholm Regional Ethics Vetting Board.

## Results

We identified 9,582 new cases of prostate cancer among workers with at least one clinic visit prior to diagnosis. Mean age at diagnosis was 70.2 years. During the study period 4,758 (50%) men died. Of those, 52% (n=2,489) died of prostate cancer. The mean time from study entry/baseline exam to prostate cancer diagnosis was 20.6 years (range: 1 week-33.2 years), and the mean follow-up time after diagnosis was 4.5 years. 869 cases (9%) were diagnosed between 1972 and 1984, 2,674 (28%) between 1985 and 1994, and 6,039 (63%) from 1995 to 2004. Among the 5,346 cases included in The National Prostate Cancer Register (NPCR) of Sweden, the median PSA at diagnosis was 15.0 ng/ml, and 20% had Gleason 8-10 disease. 20% of cases were diagnosed with distant metastases and another 10% with regionally spread disease.

**Table 1** describes the study population according to tobacco use at study entry. Never users accounted for 29% of the population, while 5% were exclusive snus users, 50% were exclusive smokers (cigarettes, pipe, and/or cigars), and 16% both used snus and smoked. Mean age at diagnosis was slightly higher among exclusive snus users and slightly lower among users of both. Mean BMI at study entry was slightly higher among exclusive snus users than in other groups. Mean duration of snus use at baseline among exclusive snus users was 24.3 years and 15.2 years among users of both. Mean duration of smoking was 24.7 years among exclusive smokers and 23.0 years among users of both. The frequency of Gleason score 8-10 at diagnosis was similar across groups. PSA at diagnosis was 15.0 ng/mL among never users, 16.0 ng/mL among exclusive smokers, 16.0 ng/mL among exclusive snus users, and 13.6 ng/mL among users of both. Users of both snus and smoking were slightly more likely to be in lower risk groups at diagnosis, while distribution of risk groups was similar in the other three groups.

Compared to never users, men in all three groups of tobacco use were at increased risk of overall mortality (**Table 2**; HR 1.19, 95% CI: 1.04-1.37 for exclusive snus; HR 1.17, 95% CI: 1.09-1.26 for

exclusive smoking; HR 1.17, 95% CI: 1.06-1.28 for both). Exclusive snus users and exclusive smokers were at increased risk of prostate cancer-specific mortality, with a hazard ratio of 1.24 (95% CI: 1.03-1.49) for exclusive snus users and 1.15, (95% CI: 1.05-1.27) for exclusive smokers. Users of both were at non-significantly increased risk of prostate cancer death (HR 1.08, 95% CI: 0.95-1.23).

When the analysis was restricted to men with available tumor characteristics, results were largely similar, though some associations were no longer statistically significant, likely due to smaller numbers of events. (**Table 2**)

In the subgroup of men diagnosed with non-metastatic disease, men in all three groups of tobacco use were at increased risk of total mortality, with somewhat greater hazard ratios than observed for the total patient cohort (**Table 2**). The association between tobacco use and prostate cancer-specific death was also more pronounced. Exclusive snus users had a hazard ratio of 3.17, 95% CI: 1.66-6.06, exclusive smokers had a hazard ratio of 1.33, 95% CI: 0.85-2.08, and users of both had a hazard ratio of 1.93, 95% CI: 1.11-3.35.

## Discussion

Data from this large cohort study provides further support that tobacco use increases the risk of total mortality as well as prostate cancer-specific mortality among men newly diagnosed with prostate cancer.<sup>2-4</sup> For the first time, we also show an excess risk of overall and cancer-specific mortality among snus users, a noteworthy observation as snus is generally considered, and has been promoted, as a healthier and less carcinogenic alternative to smoking.<sup>10-13</sup> Indeed, among men who never smoked, snus use was positively associated with overall and prostate cancer-specific mortality.

A previous study in this cohort<sup>19</sup> among all cancer cases found an excess risk of cancer specific death among exclusive snus users, exclusive smokers, and combined users (snus and smoking), with a 24% increased risk among exclusive snus users. A study in Uppsala county, Sweden among men without cancer at baseline found an increased risk of all-cause mortality for those who reported any snus use, and a suggestion of an increased risk of cancer mortality for exclusive snus use (HR: 1.28, 95% CI: 0.96-1.69).<sup>20</sup>

There are many hypothesized mechanisms behind the association between snus use and prostate cancer progression, although the exact mechanism is unclear. While snus users are not exposed to the combustion products of tobacco, they are exposed to nicotine and to multiple carcinogens present in smokeless tobacco, such as tobacco-specific nitrosamines (TSNAs), polycyclic aromatic hydrocarbons (PAHs), volatile aldehydes, and N-nitrosamino acids (NNAs), which have been shown to form DNA adducts.<sup>21-25</sup> Furthermore, they also contain aldehydes and metals, which have been associated with inflammation and increased cell proliferation.<sup>25</sup>

Snus users have blood levels of nicotine metabolites similar to those seen in cigarette smokers.<sup>26</sup> Experimental evidence from *in vitro* and *in vivo* studies suggests that nicotine, while not carcinogenic, may promote cancer progression at concentrations relevant to tobacco use.<sup>27</sup> Nicotine binds to nicotinic

acetylcholine receptors (nAChR), which are present in various nonneuronal tissues.<sup>28</sup> A broad range of laboratory findings show that nicotine promotes cell proliferation and angiogenesis through its effects on nAChR in breast and lung cancer cell lines and in animal models of breast and colon cancer.<sup>7, 27, 29-35</sup>

Nicotine and nAChR expression has not been studied in prostate cancer models. However, a variety of signaling cascades downstream of nAChR play important roles in prostate cancer, including the c-Src, PI3K/AKT/mTOR, MAPK, and HIF-1 $\alpha$ .<sup>36-41</sup> These effects of nicotine could explain, in part, the association of smoking and snus with prostate cancer progression, but lack of association with cancer incidence.

Beyond nicotine, snus users are exposed to multiple tobacco-derived carcinogens. The TSNA content of snus is comparable to cigarette smoke.<sup>9, 42-44</sup> TSNA, including 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) and N'-nitrosonornicotine (NNN), are carcinogenic compounds formed during the processing of tobacco, and have been shown to cause lung, nasal, and esophageal tumors in various rodent models and to induce DNA adducts.<sup>22,45</sup> In addition, these compounds, like their precursor nicotine, bind to nAChR to promote tumor progression through multiple pathways.<sup>46, 47</sup>

While our results are suggestive, particularly in light of previous cell line studies, animal models and epidemiological studies, it is important to note several important limitations of this work. First, we have only a single assessment of tobacco use, recorded an average of 20 years before cancer diagnosis. This leaves room for substantial misclassification of tobacco use closer to and after the cancer diagnosis. It is likely that some users in all three tobacco use categories quit after the exam or after their diagnosis, given general trends over time. Such measurement error would result in an underestimation of the true effect of snus use and smoking on mortality. In addition, if smokers were more likely to quit than snus users, due to the perception that snus is less harmful, then the extent of the underestimation might be greater for smoking groups than for the exclusive snus group. The lack of detailed smoking history prevents us from evaluating a dose-response relationship or examining whether quitting is eventually

associated with lower prostate cancer mortality, which is an important public health question. However, despite these limitations of the data, this unique cohort adds to our understanding of tobacco and prostate cancer survival.

Our study is also limited by the lack of covariate data, such as leisure-time physical activity. However, because few lifestyle factors have been strongly related to prostate cancer mortality, the lack of lifestyle information is less likely to substantially influence the results than for other causes of mortality. We did adjust for BMI at study entry, as exclusive snus users had slightly higher mean BMI at this point; however, we lack information on BMI at later time points, which may be important given evidence that obesity plays a role in prostate cancer progression.<sup>48</sup> Unfortunately, we did not have information on the use of PSA screening among the men in this study, preventing us from ruling out differences in screening according to tobacco use at study entry. However, median PSA at diagnosis was similar between tobacco use groups, and the associations remained when we adjusted for stage and grade, and when we restricted the analysis to patients in lower-risk categories at diagnosis. With that said, the number of prostate cancer deaths among exclusive snus users is low when restricted to lower-risk categories.

In addition to adding to our understanding of the biology of prostate cancer, our findings have important implications for public health policy. Snus has been marketed as a less harmful alternative to smoking,<sup>10-13, 49,50</sup> and is sometimes promoted as a smoking cessation aid, despite several studies finding no benefit.<sup>51</sup> Indeed, the US Food and Drug Administration (FDA) received and rejected an application from Swedish manufacturers seeking approval to modify language on snus warning labeling stating: "No tobacco product is safe but this product presents substantially lower risks to health than cigarettes."<sup>52</sup> However, the content of TSNA and other carcinogens in snus is quite variable and is not labeled or routinely monitored.<sup>24</sup> Other smokeless tobacco products are also increasing in popularity. Particularly, e-cigarettes are increasingly common, with recent surveys reporting 12.6% of adults ever tried an e-

cigarette and e-cigarette use tripling among adolescents in just one year.<sup>53-58</sup> In addition, a recent survey of high school students found those who had ever used e-cigarettes were more likely to report use of combustible tobacco products.<sup>59</sup> E-cigarettes are marketed as safer than cigarette smoking, with companies claiming they are healthier, cheaper and cleaner than cigarettes.<sup>60, 61</sup> However, the concentration of nicotine in e-cigarette liquid varies widely across and even within products,<sup>62</sup> and some e-cigarettes also contain TSNA and other toxicants.<sup>63</sup>

### Conclusions

We found that a history of both smoking and snus use was associated with increased risk of prostate cancer-specific mortality and total mortality among men with prostate cancer in a large cohort in Sweden. Our results suggest that nicotine or other carcinogens in smokeless tobacco products may promote cancer progression independent of the combustion products of tobacco smoke, and may have implications for the regulation of smokeless tobacco products.

### Funding support

KMW, JRR, and LAM are supported by Prostate Cancer Foundation Young Investigator Awards. SCM is supported by a T32 training award from the National Cancer Institute (NIH T32 CA09001).

# June Facebook Posts (partial)

This month, we're taking you on a late night adventure. How the night plays out is in your hands. Each new post offers you a decision to make, and remember... with General Snus, anything is possible. Adventure kicks off in just 2 days.

WARNING: This product can cause mouth cancer.

Your first run with General Snus starts now.

You're on your way out to meet a group of friends at a bar. But the night wouldn't be complete without a can of your favorite snus. You stop at your go-to convenience store to grab some. The girl at the register with the snow owl tattoo actually remembers you and calls you by name. Their she asks, "Will it be General Mint or White?" Comment to cast your vote.

WARNING: This product can cause mouth cancer.

Mint it is. There's only one can left at the store, and it's all yours. But the guy wearing a powder blue track suit in line behind you wanted Mint, too. Really wanted it. He approaches you and offers you two tickets to a huge concert up the street for your can. Do you take him up on his offer and get White instead? Or hang on to your Mint? Comment to cast your vote.

WARNING: This product can cause mouth cancer.

Tickets it is. The show's about to start, and you've got a can of White plus two incredible seats waiting for you. The only question now is... who do you bring? Your best friend who loves shows but will definitely need to sleep out for a few smoke breaks, or the tattooed girl at the register? You're holding the tickets, standing in the doorway. Text your friend or go back in and ask the girl? Comment to cast your vote.

WARNING: This product can cause mouth cancer.

Looks like you and your friend are show-bound. He meets you at the venue and stops to have a quick smoke before heading in. You toss in a pouch just as your hear the opener take the stage inside. Do you stand outside and wait for your friend, or go in and catch the first notes? Comment to cast your vote.

WARNING: This product can cause mouth cancer.

General Snus

Published by Jen Cian Mulligan (1) · June 21 at 8:30am ·

You sick around. You're not one to ditch. While you stand and wait, you hear the crowd roar. You turn towards the entrance to catch a glimpse and instead catch sight of a powder blue track suit. It's the guy from the store. He sees you and motions for you to follow. But those big your friend has just introduced himself to a girl standing nearby. Do you grab him and go, or play his wingman? Comment to cast your vote.

WARNING: This product can cause mouth cancer.

This guy is full of surprises... and you're game. You grab your friend and run to catch up. Turns out he's got an in with the sound guy, and he's taking you and your friend backstage. On your way there, you walk past a door marked with a big gold star. Through the crack you see the band getting ready to head on stage. Do you give track suit the slip and go introduce yourself? Or do you head to the best seats in the house? Comment to cast your vote.

WARNING: This product can cause mouth cancer.

Pass up a view like that? No way. But in all the excitement, you realize you ended up on the wrong side of the stage. Before you have a chance to correct yourselves, you bump into the manager who mistakes you and your friend for a few of the back-ups. The show is starting, and he pushes you forward. Now that you're in the spotlight, do you grab a mic and join the singers or hop in with the background dancers? Comment to cast your vote.

WARNING: This product can cause mouth cancer.

You and your friend killed it on stage. Even the band noticed your enthusiasm. They invite you to their exclusive after-party, but only after they pick up some smokes. You remember that can in your pocket from earlier, and there's enough to go around. So with pouches in, you all leave together to trish off a legendary evening. With General, there's no telling where the night will take you next. The question now is where will you take your General Snus?

POS

## Ice Chest Sign POS (May 2016)

The advertisement features a blue background with water droplets. At the top center is a shield logo with a stylized 'G'. Below it, the text "EXPERTLY CRAFTED. PERFECTLY CHILLED." is written in bold, black, sans-serif capital letters. In the lower-left quadrant, there is an open tin of General Swedish Snus. The lid is black with the "General" logo in white script, "SWEDISH SNUS" in white sans-serif, and "MINT | 24 PORTIONS" on a blue band. The open tin shows several white snus packets arranged in a circular pattern. To the right of the tin, the text "LOOK FOR THE GENERAL SNUS CHILLER BEHIND THE COUNTER." is written in black, sans-serif capital letters, flanked by horizontal lines. At the bottom, a white rectangular box with a black border contains the text "WARNING: This product can cause mouth cancer." in black, sans-serif capital letters.
